CHAPTER 1

General

1.1 Introduction

pgRouting is an extension of PostGIS\(^1\) and PostgreSQL\(^2\) geospatial database and adds routing and other network analysis functionality. A predecessor of pgRouting – pgDijkstra, written by Sylvain Pasche from Camptocamp\(^3\), was later extended by Orkney\(^4\) and renamed to pgRouting. The project is now supported and maintained by Georepublic\(^5\), iMaptools\(^6\) and a broad user community.

pgRouting is an OSGeo Labs\(^7\) project of the OSGeo Foundation\(^8\) and included on OSGeo Live\(^9\).

1.1.1 License

The following licenses can be found in pgRouting:

<table>
<thead>
<tr>
<th>License</th>
<th>Description</th>

- Orkney
- Paragon Corporation

1.1.3 Inside

![Boost Graph Inside](image)

Fig. 1.1: Boost Graph Inside

1.1.4 More Information

- The latest software, documentation and news items are available at the pgRouting web site [http://pgrouting.org](http://pgrouting.org).
- PostgreSQL database server at the PostgreSQL main site [http://www.postgresql.org](http://www.postgresql.org).
- PostGIS extension at the PostGIS project web site [http://postgis.net](http://postgis.net).

1.2 Installation

This is a basic guide to download and install pgRouting.

**Note:** additional notes can be found in [Installation Notes](#)

1.2.1 Download

Binary packages are provided for the current version on the following platforms:

Windows

Winnie Bot Builds:
- Winnie PostgreSQL 9.2-9.5 32-bit/64-bit\(^5\)

Production Builds:
- Production builds are part of the Spatial Extensions/PostGIS Bundle available via Application StackBuilder
- Can also get PostGIS Bundle from\(^16\)

Ubuntu/Debian

Ubuntu packages are available in Launchpad repositories:
- stable https://launchpad.net/~georepublic/+archive/pgrouting
- unstable https://launchpad.net/~georepublic/+archive/pgrouting-unstable

```bash
# Add pgRouting launchpad repository ("stable" or "unstable")
sudo add-apt-repository ppa:georepublic/pgrouting[~unstable]
sudo apt-get update

# Install pgRouting packages
sudo apt-get install postgresql-9.1-pgrouting
```

Use UbuntuGIS-unstable PPA\(^17\) to install PostGIS 2.0.

RHEL/CentOS/Fedora

- Fedora RPM’s: https://admin.fedoraproject.org/pkgdb/acls/name/pgRouting

FreeBSD

pgRouting can be installed via ports:

```bash
cd /usr/ports/databases/pgRouting
make install clean
```

OS X

- Homebrew

```bash
brew install pgrouting
```

Source Package

You can find all the pgRouting Releases:

https://github.com/pgRouting/pgrouting/releases

See Build Guide to build the binaries from the source.

---

\(^5\)http://postgis.net/windows_downloads
\(^6\)http://download.osgeo.org/postgis/windows/
\(^7\)https://launchpad.net/ubuntugis/+archive/ubuntugis-unstable
Using Git

Git protocol (read-only):

```
git clone git://github.com/pgRouting/pgrouting.git
```

HTTPS protocol (read-only):

```
git clone https://github.com/pgRouting/pgrouting.git
```

See Build Guide to build the binaries from the source.

1.2.2 Installing in the database

pgRouting is an extension.

```
CREATE EXTENSION postgis;
CREATE EXTENSION pgrouting;
```

1.2.3 Upgrading the database

To upgrade pgRouting to version 2.1.0 use the following command:

```
ALTER EXTENSION pgrouting UPDATE TO "2.1.0";
```

1.3 Build Guide

1.3.1 Dependencies

To be able to compile pgRouting make sure that the following dependencies are met:

- C and C++0x compilers
- Postgresql version >= 9.1
- PostGIS version >= 2.0
- The Boost Graph Library (BGL). Version >= 1.55
- CMake >= 2.8.8
- CGAL >= 4.2
- (optional, for Documentation) Sphinx >= 1.1
- (optional, for Documentation as PDF) Latex >= [TBD]

1.3.2 Configuration

PgRouting uses the cmake system to do the configuration.
The following instructions start from `path/to/pgrouting/`

Create the build directory

```
$ mkdir build
```

To configure:

```
$ cd build
$ cmake -L ..
```
Configurable variables

The documentation configurable variables are:

- **WITH_DOC** BOOL=OFF – Turn on/off building the documentation
- **BUILD_HTML** BOOL=ON – If WITH_DOC=ON, turn on/off building HTML
- **BUILD_LATEX** BOOL=OFF – If WITH_DOC=ON, turn on/off building PDF
- **BUILD_MAN** BOOL=OFF – If WITH_DOC=ON, turn on/off building MAN pages

Configuring with documentation

```
$ cmake -DWITH_DOC=ON ..
```

**Note:** Most of the effort of the documentation has been on the html files.

1.3.3 Building

Using `make` to build the code and the documentation.

The following instructions start from `path/to/pgrouting/build`

```
$ make             # build the code but not the documentation
$ make doc         # build only the documentation
$ make all doc     # build both the code and the documentation
```

1.3.4 Installation and reinstallation

We have tested on several platforms. For installing or reinstalling all the steps are needed.

**Warning:** The sql signatures are configured and build in the `cmake` command.

For MinGW on Windows

```
$ mkdir build
$ cd build
$ cmake -G"MSYS Makefiles" ..
$ make
$ make install
```

For Linux

The following instructions start from `path/to/pgrouting`

```
$ mkdir build
$ cd build
$ cmake ..
$ make
$ sudo make install
```
1.4 Support

pgRouting community support is available through website\(^{18}\), documentation\(^{19}\), tutorials, mailing lists and others. If you're looking for commercial support, find below a list of companies providing pgRouting development and consulting services.

1.4.1 Reporting Problems

Bugs are reported and managed in an issue tracker\(^{20}\). Please follow these steps:

1. Search the tickets to see if your problem has already been reported. If so, add any extra context you might have found, or at least indicate that you too are having the problem. This will help us prioritize common issues.

2. If your problem is unreported, create a new issue\(^{21}\) for it.

3. In your report include explicit instructions to replicate your issue. The best tickets include the exact SQL necessary to replicate a problem.

4. If you can test older versions of PostGIS for your problem, please do. On your ticket, note the earliest version the problem appears.

5. For the versions where you can replicate the problem, note the operating system and version of pgRouting, PostGIS and PostgreSQL.

6. It is recommended to use the following wrapper on the problem to pin point the step that is causing the problem.

\[
\begin{align*}
\text{SET client_min_messages TO debug;}<\text{your code}> \\
\text{SET client_min_messages TO notice;}
\end{align*}
\]

1.4.2 Mailing List and GIS StackExchange

There are two mailing lists for pgRouting hosted on OSGeo mailing list server:

- User mailing list: http://lists.osgeo.org/mailman/listinfo/pgrouting-users
- Developer mailing list: http://lists.osgeo.org/mailman/listinfo/pgrouting-dev

For general questions and topics about how to use pgRouting, please write to the user mailing list.

You can also ask at GIS StackExchange\(^{22}\) and tag the question with pgrouting. Find all questions tagged with pgrouting under http://gis.stackexchange.com/questions/tagged/pgrouting or subscribe to the pgRouting questions feed\(^{23}\).

1.4.3 Commercial Support

For users who require professional support, development and consulting services, consider contacting any of the following organizations, which have significantly contributed to the development of pgRouting:

\(^{18}\)http://www.pgrouting.org
\(^{19}\)http://docs.pgrouting.org
\(^{20}\)https://github.com/pgrouting/pgrouting/issues
\(^{21}\)https://github.com/pgRouting/pgRouting/issues/new
\(^{22}\)http://gis.stackexchange.com/
\(^{23}\)http://gis.stackexchange.com/feeds/tag?tagnames=pgrouting&sort=newest

2.1 Tutorial

Getting started

• How to create a database to use for our project
• How to load some data
• How to build a topology
• How to check your graph for errors
• How to compute a route
• How to use other tools to view your graph and route
• How to create a web app

Advanced Topics

• Routing Topology for an overview of a topology for routing algorithms.
• Graph Analytics for an overview of the analysis of a graph.
• Dictionary of columns & Custom Query that is used in the routing algorithms.
• Performance Tips to improve your performance.

2.1.1 Getting Started

This is a simple guide to walk you through the steps of getting started with pgRouting. In this guide we will cover:

• How to create a database to use for our project
• How to load some data
• How to build a topology
• How to check your graph for errors
• How to compute a route
• How to use other tools to view your graph and route
• How to create a web app

How to create a database to use for our project

The first thing we need to do is create a database and load pgRouting in the database. Typically you will create a database for each project. Once you have a database to work in, you can load your data and build your application in that database. This makes it easy to move your project later if you want to to say a production server.

For Postgresql 9.1 and later versions

```bash
createdb mydatabase
psql mydatabase -c "create extension postgis"
psql mydatabase -c "create extension pgRouting"
```

For older versions of postgresql

```bash
createdb -T template1 template_postgis
psql template_postgis -c "create language plpgsql"
psql template_postgis -f /usr/share/postgresql/9.0/contrib/postgis-1.5/postgis.sql
psql template_postgis -f /usr/share/postgresql/9.0/contrib/postgis-1.5/spatial_ref_sys.sql
psql template_postgis -f /usr/share/postgresql/9.0/contrib/postgis_comments.sql

createdb -T template_postgis template_pgrouting
psql template_pgrouting -f /usr/share/postgresql/9.0/contrib/pgRouting-2.0/pgRouting.sql

createdb -T template_pgrouting mydatabase
```

How to load some data

How you load your data will depend in what form it comes it. There are various OpenSource tools that can help you, like:

- **shp2pgsql**
  - this is the postgresql shapefile loader
- **ogr2ogr**
  - this is a vector data conversion utility
- **osm2pgsql**
  - this is a tool for loading OSM data into postgresql

So these tools and probably others will allow you to read vector data and and can load that data into your database as a table of some kind. At this point you need to know a little about your data structure and content. One easy way to browse your data table is with pgAdmin3 or phpPgAdmin.

How to build a topology

Next we need to build a topology for our street data. What this means is that for any given edge in your street data the ends of that edge will be connected to a unique node and to other edges that are also connected to that same unique node. Once all the edges are connected to nodes we have a graph that can be used for routing with pgRouting. We provide a tools the will help with this:
select pgr_createTopology('myroads', 0.000001);

See `pgr_createTopology` for more information.

How to check your graph for errors

There are lots of possible sources for errors in a graph. The data that you started with may not have been designed with routing in mind. A graph as some very specific requirments. One it that it is NODED, this means that except for some very specific use cases, each road segments starts and ends at a node and that in general is does not cross another road segment that it should be connected to.

There can be other errors like the direction of a one-way street being entered in the wrong direction. We do not have tools to search for all possible errors but we have some basic tools that might help.

```sql
select pgr_analyzegeograph('myroads', 0.000001);
select pgr_analyzeoneway('myroads', s_in_rules, s_out_rules, t_in_rules, t_out_rules, direction)
```

See `Graph Analytics` for more information.

If your data needs to be NODED, we have a tool that can help for that also.

See `pgr_nodeNetwork` for more information.

How to compute a route

Once you have all the prep work done above, computing a route is fairly easy. We have a lot of different algorithms but they can work with your prepared road network. The general form of a route query is:

```sql
select pgr_<algorithm>(<SQL for edges>, start, end, <additonal options>)
```

As you can see this is fairly straight forward and you can look the specific algorithms for the details on how to use them. What you get as a result from these queries will be a set of record of type `pgr_costResult[]` or `pgr_geomResult[]`. These results have information like edge id and/or the node id along with the cost or geometry for the step in the path from start to end. Using the ids you can join these result back to your edge table to get more information about each step in the path.

- See also `pgr_costResult[]` and `pgr_geomResult[]`.

2.1.2 Routing Topology

Author  Stephen Woodbridge <woodbri@swoodbridge.com>

Copyright  Stephen Woodbridge. The source code is released under the MIT-X license.

Overview

Typically when GIS files are loaded into the data database for use with pgRouting they do not have topology information associated with them. To create a useful topology the data needs to be “noded”. This means that where two or more roads form an intersection there it needs to be a node at the intersection and all the road segments need to be broken at the intersection, assuming that you can navigate from any of these segments to any other segment via that intersection.

You can use the `graph analysis functions` to help you see where you might have topology problems in your data. If you need to node your data, we also have a function `pgr_nodeNetwork()` that might work for you. This function splits ALL crossing segments and nodes them. There are some cases where this might NOT be the right thing to do.

---

1 woodbri@swoodbridge.com
For example, when you have an overpass and underpass intersection, you do not want these noded, but pgr_nodeNetwork does not know that is the case and will node them which is not good because then the router will be able to turn off the overpass onto the underpass like it was a flat 2D intersection. To deal with this problem some data sets use z-levels at these types of intersections and other data might not node these intersection which would be ok.

For those cases where topology needs to be added the following functions may be useful. One way to prep the data for pgRouting is to add the following columns to your table and then populate them as appropriate. This example makes a lot of assumption like that you original data tables already has certain columns in it like `one_way`, `fcc`, and possibly others and that they contain specific data values. This is only to give you an idea of what you can do with your data.

```
ALTER TABLE edge_table
ADD COLUMN source integer,
ADD COLUMN target integer,
ADD COLUMN cost_len double precision,
ADD COLUMN cost_time double precision,
ADD COLUMN rcost_len double precision,
ADD COLUMN rcost_time double precision,
ADD COLUMN x1 double precision,
ADD COLUMN y1 double precision,
ADD COLUMN x2 double precision,
ADD COLUMN y2 double precision,
ADD COLUMN to_cost double precision,
ADD COLUMN rule text,
ADD COLUMN isolated integer;
```

```
SELECT pgr_createTopology('edge_table', 0.000001, 'the_geom', 'id');
```

The function `pgr_createTopology()` will create the `vertices_tmp` table and populate the `source` and `target` columns. The following example populated the remaining columns. In this example, the `fcc` column contains feature class code and the `CASE` statements converts it to an average speed.

```
UPDATE edge_table SET
  x1 = st_x(st_startpoint(the_geom)),
  y1 = st_y(st_startpoint(the_geom)),
  x2 = st_x(st_endpoint(the_geom)),
  y2 = st_y(st_endpoint(the_geom)),
  cost_len = st_length_spheroid(the_geom, 'SPHEROID[WGS84,6378137,298.25728]'),
  rcost_len = st_length_spheroid(the_geom, 'SPHEROID[WGS84,6378137,298.25728]'),
  len_km = st_length_spheroid(the_geom, 'SPHEROID[WGS84,6378137,298.25728]')/1000.0,
  len_miles = st_length_spheroid(the_geom, 'SPHEROID[WGS84,6378137,298.25728]')/1000.0 * 0.6213712,
  speed_mph = CASE
    WHEN fcc='A10' THEN 65
    WHEN fcc='A15' THEN 65
    WHEN fcc='A20' THEN 55
    WHEN fcc='A25' THEN 55
    WHEN fcc='A30' THEN 45
    WHEN fcc='A35' THEN 45
    WHEN fcc='A40' THEN 35
    WHEN fcc='A45' THEN 35
    WHEN fcc='A50' THEN 25
    WHEN fcc='A60' THEN 25
    WHEN fcc='A61' THEN 25
    WHEN fcc='A62' THEN 25
    WHEN fcc='A64' THEN 25
    WHEN fcc='A70' THEN 15
    WHEN fcc='A69' THEN 10
    ELSE null END,
  speed_kmh = CASE
    WHEN fcc='A10' THEN 104
    WHEN fcc='A15' THEN 104
    WHEN fcc='A20' THEN 88
    WHEN fcc='A25' THEN 88
    WHEN fcc='A30' THEN 72
```

Chapter 2. Tutorial
WHEN fcc='A35' THEN 72
WHEN fcc='A40' THEN 56
WHEN fcc='A45' THEN 56
WHEN fcc='A50' THEN 40
WHEN fcc='A60' THEN 50
WHEN fcc='A61' THEN 40
WHEN fcc='A62' THEN 40
WHEN fcc='A64' THEN 40
WHEN fcc='A70' THEN 25
WHEN fcc='A69' THEN 15
ELSE null END;

-- UPDATE the cost information based on oneway streets

UPDATE edge_table SET
cost_time = CASE
    WHEN one_way='TF' THEN 10000.0
    ELSE cost_len/1000.0/speed_kmh::numeric*3600.0
END,
rcost_time = CASE
    WHEN one_way='FT' THEN 10000.0
    ELSE cost_len/1000.0/speed_kmh::numeric*3600.0
END;

-- clean up the database because we have updated a lot of records

VACUUM ANALYZE VERBOSE edge_table;

Now your database should be ready to use any (most?) of the pgRouting algorithms.

- `pgr_pointToId`

### 2.1.3 Graph Analytics

**Author**  Stephen Woodbridge <woodbri@swoodbridge.com>

**Copyright**  Stephen Woodbridge. The source code is released under the MIT-X license.

**Overview**

It is common to find problems with graphs that have not been constructed fully noded or in graphs with z-levels at intersection that have been entered incorrectly. An other problem is one way streets that have been entered in the wrong direction. We can not detect errors with respect to “ground” truth, but we can look for inconsistencies and some anomalies in a graph and report them for additional inspections.

We do not current have any visualization tools for these problems, but I have used mapserver to render the graph and highlight potential problem areas. Someone familiar with graphviz might contribute tools for generating images with that.
Analyze a Graph

With \texttt{pgr\_analyzeGraph} the graph can be checked for errors. For example for table “mytab” that has “mytab\_vertices\_pgr” as the vertices table:

\begin{verbatim}
SELECT pgr_analyzeGraph('mytab', 0.000002);
NOTICE: Performing checks, please wait...
NOTICE: Analyzing for dead ends. Please wait...
NOTICE: Analyzing for gaps. Please wait...
NOTICE: Analyzing for isolated edges. Please wait...
NOTICE: Analyzing for ring geometries. Please wait...
NOTICE: Analyzing for intersections. Please wait...
NOTICE: ANALYSIS RESULTS FOR SELECTED EDGES:
NOTICE: Isolated segments: 158
NOTICE: Dead ends: 20028
NOTICE: Potential gaps found near dead ends: 527
NOTICE: Intersections detected: 2560
NOTICE: Ring geometries: 0
pgr_analyzeGraph
----------
OK
(1 row)
\end{verbatim}

In the vertices table “mytab\_vertices\_pgr”:

- Deadends are indentified by \texttt{cnt=1}
- Potential gap problems are identified with \texttt{chk=1}.

\begin{verbatim}
SELECT count(*) as deadends FROM mytab\_vertices\_pgr WHERE cnt = 1;
deadends
---------
20028
(1 row)
SELECT count(*) as gaps FROM mytab\_vertices\_pgr WHERE chk = 1;
gaps
-----
527
(1 row)
\end{verbatim}

For isolated road segments, for example, a segment where both ends are deadends. you can find these with the following query:

\begin{verbatim}
SELECT * FROM mytab a, mytab\_vertices\_pgr b, mytab\_vertices\_pgr c
WHERE a.source=b.id AND b.cnt=1 AND a.target=c.id AND c.cnt=1;
\end{verbatim}

If you want to visualize these on a graphic image, then you can use something like mapserver to render the edges and the vertices and style based on \texttt{cnt} or if they are isolated, etc. You can also do this with a tool like graphviz, or geoserver or other similar tools.

Analyze One Way Streets

\texttt{pgr\_analyzeOneway} analyzes one way streets in a graph and identifies any flipped segments. Basically if you count the edges coming into a node and the edges exiting a node the number has to be greater than one.

This query will add two columns to the vertices\_tmp table \texttt{ein int} and \texttt{eout int} and populate it with the appropriate counts. After running this on a graph you can identify nodes with potential problems with the following query.

The rules are defined as an array of text strings that if match the \texttt{col} value would be counted as true for the source or target in or out condition.
Example

Lets assume we have a table “st” of edges and a column “one_way” that might have values like:

• ‘FT’ - oneway from the source to the target node.
• ‘TF’ - oneway from the target to the source node.
• ‘B’ - two way street.
• ‘’ - empty field, assume twoway.
• <NULL> - NULL field, use two_way_if_null flag.

Then we could form the following query to analyze the oneway streets for errors.

```sql
SELECT pgr_analyzeOneway('mytab',
 ARRAY['', 'B', 'TF'],
 ARRAY['', 'B', 'FT'],
 ARRAY['', 'B', 'FT'],
 ARRAY['', 'B', 'TF'],
);
```

-- now we can see the problem nodes
SELECT * FROM mytab_vertices_pgr WHERE ein=0 OR eout=0;

-- and the problem edges connected to those nodes
SELECT gid FROM mytab a, mytab_vertices_pgr b
WHERE a. source=b.id AND ein=0 OR eout=0
UNION
SELECT gid FROM mytab a, mytab_vertices_pgr b
WHERE a. target=b.id AND ein=0 OR eout=0;

Typically these problems are generated by a break in the network, the one way direction set wrong, maybe an error related to z-levels or a network that is not properly noded.

The above tools do not detect all network issues, but they will identify some common problems. There are other problems that are hard to detect because they are more global in nature like multiple disconnected networks. Think of an island with a road network that is not connected to the mainland network because the bridge or ferry routes are missing.

• pgr_analyzeOneway
• pgr_nodeNetwork

2.1.4 Dictionary of columns & Custom Query

**path** a sequence of vertices/edges from A to B.

**route** a sequence of paths.

Description of the edges_sql query

**edges_sql** an SQL query, which should return a set of rows with the following columns:

- **id** ANY-INTEGER identifier of the edge.
- **source** ANY-INTEGER identifier of the first end point vertex of the edge.
- **target** ANY-INTEGER identifier of the second end pont vertex of the edge.
- **cost** ANY-NUMERICAL weight of the edge (source, target), if negative: edge (source, target) does not exist, therefore it’s not part of the graph.
reverse_cost ANY-NUMERICAL (optional) weight of the edge (target, source), if negative: edge (target, source) does not exist, therefore it’s not part of the graph.

Where:

ANY-INTEGER  smallint, int, bigint
ANY-NUMERICAL  smallint, int, bigint, real, float

Description of the parameters of the signatures

edges_sql TEXT SQL query as described above.
start_vid BIGINT identifier of the starting vertex of the path.
start_vids array[ANY-INTEGER] array of identifiers of starting vertices.
end_vid BIGINT identifier of the ending vertex of the path.
end_vids array[ANY-INTEGER] array of identifiers of ending vertices.
directed boolean (optional). When false the graph is considered as Undirected. Default is true which considers the graph as Directed.

Description of the return values

Returns set of (seq [, start_vid ] [, end_vid ] , node, edge, cost, agg_cost)

seq INTEGER is a sequential value starting from 1.
route_seq INTEGER relative position in the route. Has value 1 for the beginning of a route.
route_id INTEGER id of the route.
path_seq INTEGER relative position in the path. Has value 1 for the beginning of a path.
path_id INTEGER id of the path.
start_vid BIGINT id of the starting vertex. Used when multiple starting vertices are in the query.
end_vid BIGINT id of the ending vertex. Used when multiple ending vertices are in the query.
node BIGINT id of the node in the path from start_v to end_v.
edge BIGINT id of the edge used to go from node to the next node in the path sequence. -1 for the last node of the path.
cost FLOAT cost to traverse from node using edge to the next node in the path sequence.
agg_cost FLOAT total cost from start_v to node.

Descriptions for version 2.0 signatures

In general, the routing algorithms need an SQL query that contain one or more of the following required columns with the preferred type:

id int4
source int4
target int4
cost float8
reverse_cost float8
x float8
y float8
\textbf{SELECT} source, target, cost FROM edge_table;
\textbf{SELECT} id, source, target, cost FROM edge_table;
\textbf{SELECT} id, source, target, cost, x1, y1, x2, y2, reverse_cost FROM edge_table

When the edge table has a different name to represent the required columns:

\textbf{SELECT} src as source, target, cost FROM othertable;
\textbf{SELECT} gid as id, src as source, target, cost FROM othertable;
\textbf{SELECT} gid as id, src as source, target, cost, fromX as x1, fromY as y1, toX as x2, toY as y2, Rcost as reverse_cost FROM othertable;

The topology functions use the same names for id, source and target columns of the edge table. The following parameters have as default value:

- \textbf{id} \texttt{int4 Default id}
- \textbf{source} \texttt{int4 Default source}
- \textbf{target} \texttt{int4 Default target}
- \textbf{the\_geom} \texttt{text Default the\_geom}
- \textbf{oneway} \texttt{text Default oneway}
- \textbf{rows\_where} \texttt{text Default true to indicate all rows (this is not a column)}

The following parameters do not have a default value and when used they have to be inserted in strict order:

- \textbf{edge\_table} \texttt{text}
- \textbf{tolerance} \texttt{float8}
- \textbf{s\_in\_rules} \texttt{text\[\]}
- \textbf{s\_out\_rules} \texttt{text\[\]}
- \textbf{t\_in\_rules} \texttt{text\[\]}
- \textbf{t\_out\_rules} \texttt{text\[\]}

When the columns required have the default names this can be used (\texttt{pgr\_func} is to represent a topology function)

\texttt{pgr\_func('edge\_table') \hspace{1cm} \textit{-- when tolerance is not required}}
\texttt{pgr\_func('edge\_table', 0.001) \hspace{1cm} \textit{-- when tolerance is required}}
\texttt{\hspace{1cm} \textit{\texttt{-- s\_in\_rule, s\_out\_rule, st\_in\_rules, t\_out\_rules are required}}}
\texttt{\textbf{SELECT} pgr\_analyze\_oneway('edge\_table', ARRAY[', 'B', 'TF'], ARRAY[', 'B', 'FT'], ARRAY[', 'B', 'FT'], ARRAY[', 'B', 'TF'])}

When the columns required do not have the default names it's strongly recommended to use the \textit{named notation}.

\texttt{pgr\_func('othertable', id:='gid', source:='src', the\_geom:='mygeom')}  
\texttt{pgr\_func('othertable', 0.001, the\_geom:='mygeom', id:='gid', source:='src')}  
\texttt{\textbf{SELECT} pgr\_analyze\_oneway('othertable', ARRAY[', 'B', 'TF'], ARRAY[', 'B', 'FT'], ARRAY[', 'B', 'FT'], ARRAY[', 'B', 'TF'], \hspace{1cm} source:='src', oneway:='dir')}  

\subsection*{2.1.5 Performance Tips}

\textbf{For the Routing functions:}
Note: To get faster results bound your queries to the area of interest of routing to have, for example, no more than one million rows.

For the topology functions:

When “you know” that you are going to remove a set of edges from the edges table, and without those edges you are going to use a routing function you can do the following:

Analyse the new topology based on the actual topology:

```
pgr_analyzegraph('edge_table', rows_where:='id < 17');
```

Or create a new topology if the change is permanent:

```
pgr_createTopology('edge_table', rows_where:='id < 17');
pgr_analyzegraph('edge_table', rows_where:='id < 17');
```

Use an SQL that “removes” the edges in the routing function

```
SELECT id, source, target FROM edge_table WHERE id < 17
```

When “you know” that the route will not go out of a particular area, to speed up the process you can use a more complex SQL query like

```
SELECT id, source, target FROM edge_table WHERE id < 17 and the_geom && (SELECT st_buffer(the_geom,1) AS myarea FROM edge_table WHERE id=5)
```

Note that the same condition id < 17 is used in all cases.

2.2 Sample Data

The documentation provides very simple example queries based on a small sample network. To be able to execute the sample queries, run the following SQL commands to create a table with a small network data set.

Create table

```
CREATE TABLE edge_table (  
id serial,  
dir character varying,  
source integer,  
target integer,  
cost double precision,  
reverse_cost double precision,  
x1 double precision,  
y1 double precision,  
x2 double precision,  
y2 double precision,  
the_geom geometry
);
```

Insert network data

```
INSERT INTO edge_table (cost, reverse_cost, x1, y1, x2, y2) VALUES (1, 1, 2, 0, 2, 1);  
INSERT INTO edge_table (cost, reverse_cost, x1, y1, x2, y2) VALUES (-1, 1, 2, 1, 3, 1);  
INSERT INTO edge_table (cost, reverse_cost, x1, y1, x2, y2) VALUES (-1, 1, 3, 1, 4, 1);  
INSERT INTO edge_table (cost, reverse_cost, x1, y1, x2, y2) VALUES (1, 1, 2, 1, 2, 2);
```
Before you test a routing function use this query to fill the source and target columns.

SELECT pgr_createTopology('edge_table', 0.001);

This table is used in some of our examples

CREATE TABLE vertex_table (  
id serial,
  x double precision,
  y double precision
);

INSERT INTO vertex_table VALUES  
(1, 2, 0), (2, 2, 1), (3, 3, 1), (4, 4, 1), (5, 0, 2), (6, 1, 2), (7, 2, 2),  
(8, 3, 2), (9, 4, 2), (10, 2, 3), (11, 3, 3), (12, 4, 3), (13, 2, 4);

Network for queries marked as directed and cost and reverse_cost columns are used:

Blue colored lines with line arrows, represent the cost of the edge table. Green colored lines with filled arrows, represent the reverse_cost of the edge table.

Network for queries marked as undirected and cost and reverse_cost columns are used:

Network for queries marked as directed and only cost column is used:

Network for queries marked as undirected and only cost column is used:

2.3 User’s Recipes List

2.3.1 Comparing topology of a unnoded network with a noded network

Author  pgRouting team.

Licence  Open Source
Fig. 2.1: Graph 1: Directed, with cost and reverse cost
Fig. 2.2: Graph 2: Undirected, with cost and reverse cost
Fig. 2.3: Graph 3: Directed, with cost
Fig. 2.4: *Graph 4: Undirected, with cost*
This recipe uses the *Sample Data* network.

The purpose of this recipe is to compare a not nodded network with a nodded network.

```
SELECT pgr_createTopology('edge_table', 0.001);
SELECT pgr_analyzegraph('edge_table', 0.001);
SELECT pgr_nodeNetwork('edge_table', 0.001);
SELECT pgr_createTopology('edge_table_noded', 0.001);
SELECT pgr_analyzegraph('edge_table_noded', 0.001);
```

### 2.3.2 Handling parallels after getting a path (pgr_ksp focus)

**Author** pgRouting team.

**Licence** Open Source
The graph

Data

```
drop table if exists parallel;
CREATE TABLE parallel (  
id serial,  
source integer,  
target integer,  
cost double precision,  
reverse_cost double precision,  
x1 double precision,  
y1 double precision,  
x2 double precision,  
y2 double precision,  
the_geom geometry  
);
```
```sql
INSERT INTO parallel (x1,y1,x2,y2)
VALUES
(1,0,1,1),(1,1,1,3),(1,1,1,3),(1,1,1,3),(1,3,1,4),(1,1,-1,1),(-1,1,-1,3),(-1,3,1,3);
UPDATE parallel SET the_geom = ST_makeline(ST_point(x1,y1),ST_point(x2,y2));
UPDATE parallel SET the_geom = ST_makeline(ARRAY[ST_point(1,1),ST_point(0,2),ST_point(1,3)]) WHERE id = 3;
UPDATE parallel SET the_geom = ST_makeline(ARRAY[ST_point(1,1),ST_point(2,1),ST_point(2,3),ST_point(2,3),ST_point(2,3)]) WHERE id = 4;
UPDATE parallel SET cost = ST_length(the_geom), reverse_cost = ST_length(the_geom);
SELECT pgr_createTopology('parallel',0.001);
```

### pgr_ksp results

We ignore the costs because we want all the parallels.

```sql
SELECT seq, path_id AS route, node, edge INTO routes
  FROM pgr_ksp('select id, source, target, cost, reverse_cost from parallel', 1, 4, 3);

SELECT route, source, target, array_accum(id) as edges INTO paths
  FROM (SELECT seq, route, source, target
        FROM parallel, routes WHERE id = edge) AS r
      JOIN parallel USING (source, target)
    GROUP BY seq,route,source,target ORDER BY seq;
```

### CREATE AGGREGATE

```sql
CREATE AGGREGATE array_accum (anyelement)
(
  sfunc = array_append,
  stype = anyarray,
  initcond = '[]'
);
```

### Now lets generate a table with the parallel edges.

```sql
select distinct seq,route,source,target, array_accum(id) as edges into paths
  FROM (SELECT seq, route, source, target
        FROM parallel, routes WHERE id = edge) AS r
      JOIN parallel USING (source, target)
    GROUP BY seq,route,source,target ORDER BY seq;

SELECT route, source, targets, edges FROM paths;
```

We need an aggregate function:

```sql
route | source | target | edges
-------+--------+--------+---------
1 | 1 | 2 | {1}
2 | 1 | 2 | {1}
2 | 2 | 5 | {6}
1 | 2 | 3 | {2,3,4}
2 | 3 | 6 | {7}
1 | 3 | 4 | {5}
```

(10 rows)
Some more aggregate functions

To generate a table with all the combinations for parallel routes, we need some more aggregates

```sql
create or replace function multiply( integer, integer )
returns integer as
$$
select $1 * $2;
$$
language sql stable;
create aggregate prod(integer)
{
    sfunc = multiply,
    stype = integer,
    initcond = 1
};
```

And a function that "Expands" the table

```sql
CREATE OR REPLACE function expand_parallel_edge_paths(tab text)
returns TABLE (seq INTEGER, route INTEGER, source INTEGER, target INTEGER) AS
$body$
DECLARE
    nroutes INTEGER;
    newroutes INTEGER;
    rec record;
    seq2 INTEGER := 1;
    rnum INTEGER := 0;
BEGIN  -- get the number of distinct routes
    execute 'select count(DISTINCT route) from ' || tab INTO nroutes;
    FOR i IN 0..nroutes-1 LOOP
        -- compute the number of new routes this route will expand into
        -- this is the product of the lengths of the edges array for each route
        execute 'select prod(array_length(edges, 1))-1 from ' || quote_ident(tab) || ' where route=' || i INTO newroutes;
        -- now we generate the number of new routes for this route
        -- by repeatedly listing the route and swapping out the parallel edges
        FOR j IN 0..newroutes LOOP
            -- query the specific route
            FOR rec IN execute 'select * from ' || quote_ident(tab) || ' where route=' || i || ' order by seq'
            LOOP
                seq := seq2;
                route := rnum;
                source := rec.source;
                target := rec.target;
                -- using module arithmetic iterate through the various edge choices
                edge := rec.edges[(j % (array_length(rec.edges, 1)))+1];
```

2.3. User’s Recipes List 29
-- return a new record
RETURN next;
seq2 := seq2 + 1; -- increment the record count
END LOOP;
seq := seq2;
route := rnum;
source := rec.target;
target := -1;
edge := -1;
RETURN next; -- Insert the ending record of the route
seq2 := seq2 + 1;

rnum := rnum + 1; -- increment the route count
END LOOP;
END LOOP;
END;

$body$
language plpgsql volatile strict cost 100 rows 100;

Test it

select * from expand_parallel_edge_paths( 'paths' );

2.4 How to contribute.

To add a recipie or a wrapper

The first steps are:

- Fork the repository
- Create a branch for your recipe or wrapper
- Create your recipe file
To create the test file of your recipe

```bash
cd test
cp myrecipe.rst myrecipe.sql.test
# make your test based on your recipe
vi myrecipe.sql.test
git add myrecipe.sql.test

# create your test results file
touch myrecipe.result
git add myrecipe.result

# add your test to the file
vi test.conf
```

Leave only the SQL code on `myrecipe.sql.test` by deleting lines or by commenting lines.

To get the results of your recipe

From the root directory execute:

```bash
tools/test-runner.pl -alg recipes -ignorenotice
```

Copy the results of your recipe and paste them in the file `myrecipe.result`, and remove the “> ” from the file.

make a pull request.

```bash
git commit -a -m 'myrecipe is for this and that'
git push
```

From your fork in github make a pull request over develop

For a more complete introduction how to build a routing application read the [pgRouting Workshop](http://workshop.pgrouting.org).
3.1 pgr_version

3.1.1 Name

pgr_version — Query for pgRouting version information.

3.1.2 Synopsis

Returns a table with pgRouting version information.

```
table() pgr_version();
```

3.1.3 Description

Returns a table with:

- `version` varchar: pgRouting version
- `tag` varchar: Git tag of pgRouting build
- `hash` varchar: Git hash of pgRouting build
- `branch` varchar: Git branch of pgRouting build
- `boost` varchar: Boost version

History

- New in version 2.0.0

3.1.4 Examples

- Query for full version string

```
SELECT pgr_version();
```

pgr_version
------------------------------------------
• Query for `version` and `boost` attribute

```
SELECT version, boost FROM pgr_version();
```

<table>
<thead>
<tr>
<th>version</th>
<th>boost</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.0.0-dev</td>
<td>1.49.0</td>
</tr>
</tbody>
</table>

(1 row)

### 3.1.5 See Also

- `pgr_versionless` to compare two version numbers
4 Data Types

pgRouting Data Types

- `pgr_costResult[]` - A set of records to describe a path result with cost attribute.
- `pgr_costResult3[]` - A set of records to describe a path result with cost attribute.
- `pgr_geomResult` - A set of records to describe a path result with geometry attribute.

4.1 pgRouting Data Types

The following are commonly used data types for some of the pgRouting functions.

- `pgr_costResult[]` - A set of records to describe a path result with cost attribute.
- `pgr_costResult3[]` - A set of records to describe a path result with cost attribute.
- `pgr_geomResult` - A set of records to describe a path result with geometry attribute.

4.1.1 pgr_costResult[]

**Name**

`pgr_costResult[]` — A set of records to describe a path result with cost attribute.

**Description**

```sql
CREATE TYPE pgr_costResult AS
(
    seq integer,
    id1 integer,
    id2 integer,
    cost float8
);
```

- `seq` sequential ID indicating the path order
- `id1` generic name, to be specified by the function, typically the node id
- `id2` generic name, to be specified by the function, typically the edge id
- `cost` cost attribute
4.1.2 pgr_costResult3[] - Multiple Path Results with Cost

Name

pgr_costResult3[] — A set of records to describe a path result with cost attribute.

Description

```
CREATE TYPE pgr_costResult3 AS
(
    seq integer,
    id1 integer,
    id2 integer,
    id3 integer,
    cost float8
);
```

- **seq** sequential ID indicating the path order
- **id1** generic name, to be specified by the function, typically the path id
- **id2** generic name, to be specified by the function, typically the node id
- **id3** generic name, to be specified by the function, typically the edge id
- **cost** cost attribute

History

- New in version 2.0.0
- Replaces path_result

See Also

- Introduction

4.1.3 pgr_geomResult[]

Name

pgr_geomResult[] — A set of records to describe a path result with geometry attribute.

Description

```
CREATE TYPE pgr_geomResult AS
(
    seq integer,
    id1 integer,
    id2 integer,
    geom geometry
);
```

- **seq** sequential ID indicating the path order
- **id1** generic name, to be specified by the function
- **id2** generic name, to be specified by the function
**geom**  geometry attribute

**History**

- New in version 2.0.0
- Replaces **geoms**

**See Also**

- *Introduction*
5.1 Topology Functions

The pgRouting’s topology of a network, represented with an edge table with source and target attributes and a vertices table associated with it. Depending on the algorithm, you can create a topology or just reconstruct the vertices table. You can analyze the topology. We also provide a function to node an unoded network.

- **pgr_createTopology** - to create a topology based on the geometry.
- **pgr_createVerticesTable** - to reconstruct the vertices table based on the source and target information.
- **pgr_analyzeGraph** - to analyze the edges and vertices of the edge table.
- **pgr_analyzeOneway** - to analyze directionality of the edges.
- **pgr_nodeNetwork** - to create nodes to a not noded edge table.

### 5.1.1 pgr_createTopology

**Name**

`pgr_createTopology` — Builds a network topology based on the geometry information.

**Synopsis**

The function returns:

- **OK** after the network topology has been built and the vertices table created.
- **FAIL** when the network topology was not built due to an error.

```sql
varchar pgr_createTopology(text edge_table, double precision tolerance,
                          text the_geom='the_geom', text id='id',
                          text source='source', text target='target',
                          text rows_where='true', boolean clean=false)
```
Description

Parameters

The topology creation function accepts the following parameters:

- `edge_table` text: Network table name. (may contain the schema name AS well)
- `tolerance` float8: Snapping tolerance of disconnected edges. (in projection unit)
- `the_geom` text: Geometry column name of the network table. Default value is `the_geom`.
- `id` text: Primary key column name of the network table. Default value is `id`.
- `source` text: Source column name of the network table. Default value is `source`.
- `target` text: Target column name of the network table. Default value is `target`.
- `rows_where` text: Condition to SELECT a subset or rows. Default value is `true` to indicate all rows that where `source` or `target` have a null value, otherwise the condition is used.
- `clean` boolean: Clean any previous topology. Default value is `false`.

**Warning:** The `edge_table` will be affected
- The `source` column values will change.
- The `target` column values will change.
- An index will be created, if it doesn’t exists, to speed up the process to the following columns:
  - `id`
  - `the_geom`
  - `source`
  - `target`

The function returns:

- **OK** after the network topology has been built.
  - Creates a vertices table: `<edge_table>_vertices_pgr`.
  - Fills `id` and `the_geom` columns of the vertices table.
  - Fills the source and target columns of the edge table referencing the `id` of the vertices table.
- **FAIL** when the network topology was not built due to an error:
  - A required column of the Network table is not found or is not of the appropriate type.
  - The condition is not well formed.
  - The names of source, target or `id` are the same.
  - The SRID of the geometry could not be determined.

The Vertices Table

The vertices table is a requirement of the `pgr_analyzeGraph` and the `pgr_analyzeOneway` functions.

The structure of the vertices table is:

- `id` bigint: Identifier of the vertex.
- `cnt` integer: Number of vertices in the `edge_table` that reference this vertex. See `pgr_analyzeGraph`.
- `chk` integer: Indicator that the vertex might have a problem. See `pgr_analyzeGraph`.
- `ein` integer: Number of vertices in the `edge_table` that reference this vertex AS incoming. See `pgr_analyzeOneway`.
eout integer Number of vertices in the edge_table that reference this vertex AS outgoing. See pgr_analyzeOneway.

the_geom geometry Point geometry of the vertex.

History

• Renamed in version 2.0.0

Usage when the edge table’s columns MATCH the default values:

The simplest way to use pgr_createtopology is:

```sql
SELECT pgr_createTopology('edge_table', 0.001);
```

When the arguments are given in the order described in the parameters:

```sql
SELECT pgr_createTopology('edge_table', 0.001, 'the_geom', 'id', 'source', 'target');
```

We get the same result AS the simplest way to use the function.

**Warning:**
An error would occur when the arguments are not given in the appropriate order: In this example, the column id of the table edge_table is passed to the function AS the geometry column, and the geometry column the_geom is passed to the function AS the id column.

```sql
SELECT pgr_createTopology('edge_table', 0.001, 'id', 'the_geom', 'source', 'target');
ERROR: Can not determine the srid of the geometry “id” in table public.edge_table
```

When using the named notation

The order of the parameters do not matter:

```sql
SELECT pgr_createTopology('edge_table', 0.001, the_geom:='the_geom', id:='id', source:='source', target:='target');
SELECT pgr_createTopology('edge_table', 0.001, source:='source', id:='id', target:='target', the_geom:='the_geom');
```

Parameters defined with a default value can be omited, AS long AS the value matches the default:

```sql
SELECT pgr_createTopology('edge_table', 0.001, source:='source');
```

Selecting rows using rows_where parameter

Selecting rows based on the id.

```sql
SELECT pgr_createTopology('edge_table', 0.001, rows_where:='id < 10');
```

Selecting the rows where the geometry is near the geometry of row with id =5.

```sql
SELECT pgr_createTopology('edge_table', 0.001, rows_where:='the_geom && (SELECT st_buffer(the_geom,0.05) FROM edge_table WHERE id=5)');
```

Selecting the rows where the geometry is near the geometry of the row with gid =100 of the table othertable.

5.1. Topology Functions
DROP TABLE IF EXISTS otherTable;
CREATE TABLE otherTable AS (SELECT 100 AS gid, st_point(2.5,2.5) AS other_geom);

Usage when the edge table's columns DO NOT MATCH the default values:

For the following table

DROP TABLE IF EXISTS mytable;
CREATE TABLE mytable AS (SELECT id AS gid, the_geom AS mygeom, source AS src, target AS tgt FROM edge_table) ;

Using positional notation:

The arguments need to be given in the order described in the parameters:

SELECT pgr_createTopology('mytable',0.001,'mygeom','gid','src','tgt');

Warning:
An error would occur when the arguments are not given in the appropriate order: In this example, the column gid of the table mytable is passed to the function AS the geometry column, and the geometry column mygeom is passed to the function AS the id column.

SELECT pgr_createTopology('mytable',0.001,'gid','mygeom','src','tgt');
ERROR: Can not determine the srid of the geometry “gid” in table public.mytable

When using the named notation

The order of the parameters do not matter:

SELECT pgr_createTopology('mytable',0.001,source='src',id='gid',target='tgt',the_geom='mygeom');

In this scenario omitting a parameter would create an error because the default values for the column names do not match the column names of the table.

Selecting rows using rows_where parameter

Selecting rows based on the id.

SELECT pgr_createTopology('mytable',0.001,'mygeom','gid','src','tgt',rows_where:'gid < 10');

SELECT pgr_createTopology('mytable',0.001,source='src',id='gid',target='tgt',the_geom='mygeom',rows_where:'gid < 10');

Selecting the rows where the geometry is near the geometry of row with id=5.

SELECT pgr_createTopology('mytable',0.001,'mygeom','gid','src','tgt',rows_where:'mygeom && (SELECT st_buffer(mygeom,1) FROM mytable WHERE gid=5)');

SELECT pgr_createTopology('mytable',0.001,source='src',id='gid',target='tgt',the_geom='mygeom',rows_where:'mygeom && (SELECT st_buffer(mygeom,1) FROM mytable WHERE gid=5)');

Selecting the rows where the geometry is near the geometry of the row with gid=100 of the table otherTable.

DROP TABLE IF EXISTS otherTable;
CREATE TABLE otherTable AS (SELECT 100 AS gid, st_point(2.5,2.5) AS other_geom);

SELECT pgr_createTopology('mytable',0.001,'mygeom','gid','src','tgt',rows_where:'mygeom && (SELECT st_buffer(other_geom,1) FROM otherTable WHERE gid=100)');
Examples

```sql
SELECT pgr_createTopology('edge_table', 0.001, rows_where:='id<10');
```

```

### 5.1.2 pgr_createVerticesTable

**Name**

pgr_createVerticesTable — Reconstructs the vertices table based on the source and target information.

**Synopsis**

The function returns:

- OK after the vertices table has been reconstructed.
- FAIL when the vertices table was not reconstructed due to an error.

```sql
varchar pgr_createVerticesTable(text edge_table, text the_geom:='the_geom'
    text source:='source', text target:='target', text rows_where:='true')
```

5.1. Topology Functions
Description

Parameters

The reconstruction of the vertices table function accepts the following parameters:

- **edge_table** text Network table name. (may contain the schema name as well)
- **the_geom** text Geometry column name of the network table. Default value is `the_geom`.
- **source** text Source column name of the network table. Default value is `source`.
- **target** text Target column name of the network table. Default value is `target`.
- **rows_where** text Condition to SELECT a subset or rows. Default value is `true` to indicate all rows.

**Warning:** The `edge_table` will be affected

- An index will be created, if it doesn’t exist, to speed up the process to the following columns:
  - `the_geom`
  - `source`
  - `target`

The function returns:

- **OK** after the vertices table has been reconstructed.
  - Creates a vertices table: `<edge_table>_vertices_pgr`.
  - Fills `id` and `the_geom` columns of the vertices table based on the source and target columns of the edge table.
- **FAIL** when the vertices table was not reconstructed due to an error.
  - A required column of the Network table is not found or is not of the appropriate type.
  - The condition is not well formed.
  - The names of source, target are the same.
  - The SRID of the geometry could not be determined.

The Vertices Table

The vertices table is a requirement of the `pgr_analyzeGraph` and the `pgr_analyzeOneway` functions.

The structure of the vertices table is:

- **id** bigint Identifier of the vertex.
- **cnt** integer Number of vertices in the `edge_table` that reference this vertex. See `pgr_analyzeGraph`.
- **chk** integer Indicator that the vertex might have a problem. See `pgr_analyzeGraph`.
- **ein** integer Number of vertices in the `edge_table` that reference this vertex as incoming. See `pgr_analyzeOneway`.
- **eout** integer Number of vertices in the `edge_table` that reference this vertex as outgoing. See `pgr_analyzeOneway`.
- **the_geom** geometry Point geometry of the vertex.

History

- Renamed in version 2.0.0
Usage when the edge table’s columns MATCH the default values:

The simplest way to use pgr_createVerticesTable is:

```sql
SELECT pgr_createVerticesTable('edge_table');
```

When the arguments are given in the order described in the parameters:

```sql
SELECT pgr_createVerticesTable('edge_table','the_geom','source','target');
```

We get the same result as the simplest way to use the function.

**Warning:**

An error would occur when the arguments are not given in the appropriate order: In this example, the column source column `source` of the table `mytable` is passed to the function as the geometry column, and the geometry column `the_geom` is passed to the function as the source column.

```sql
SELECT pgr_createVerticesTable('edge_table','source','the_geom','target');
```

When using the named notation

The order of the parameters do not matter:

```sql
SELECT pgr_createVerticesTable('edge_table',the_geom:='the_geom',source:='source',target:='target');
```

```sql
SELECT pgr_createVerticesTable('edge_table',source:='source',target:='target',the_geom:='the_geom');
```

Parameters defined with a default value can be omitted, as long as the value matches the default:

```sql
SELECT pgr_createVerticesTable('edge_table',source:='source');
```

Selecting rows using rows_where parameter

Selecting rows based on the id.

```sql
SELECT pgr_createVerticesTable('edge_table',rows_where:='id < 10');
```

Selecting the rows where the geometry is near the geometry of row with id=5.

```sql
SELECT pgr_createVerticesTable('edge_table',rows_where:='the_geom && (select st_buffer(the_geom,0.5) FROM edge_table WHERE id=5)');
```

Selecting the rows where the geometry is near the geometry of the row with gid=100 of the table `othertable`.

```sql
DROP TABLE IF EXISTS otherTable;
CREATE TABLE otherTable AS (SELECT 100 AS gid, st_point(2.5,2.5) AS other_geom);
SELECT pgr_createVerticesTable('edge_table',rows_where:='the_geom && (select st_buffer(other_geom,0.5) FROM otherTable WHERE gid=100)');
```

Usage when the edge table’s columns DO NOT MATCH the default values:

For the following table

```sql
DROP TABLE IF EXISTS mytable;
CREATE TABLE mytable AS (SELECT id AS gid, the_geom AS mygeom, source AS src ,target AS tgt FROM edge_table);
```

5.1. Topology Functions 45
Using positional notation:

The arguments need to be given in the order described in the parameters:

```sql
SELECT pgr_createVerticesTable('mytable','mygeom','src','tgt');
```

**Warning:**

An error would occur when the arguments are not given in the appropriate order: In this example, the column `src` of the table `mytable` is passed to the function as the geometry column, and the geometry column `mygeom` is passed to the function as the source column.

```sql
SELECT pgr_createVerticesTable('mytable','src','mygeom','tgt');
```

When using the named notation

The order of the parameters do not matter:

```sql
SELECT pgr_createVerticesTable('mytable',the_geom:='mygeom',source:'src',target:'tgt');
SELECT pgr_createVerticesTable('mytable',source:'src',target:'tgt',the_geom:='mygeom');
```

In this scenario omitting a parameter would create an error because the default values for the column names do not match the column names of the table.

Selecting rows using rows_where parameter

Selecting rows based on the gid.

```sql
SELECT pgr_createVerticesTable('mytable','mygeom','src','tgt',rows_where:='gid < 10');
SELECT pgr_createVerticesTable('mytable','src','mygeom','tgt',rows_where:='gid < 10');
```

Selecting the rows where the geometry is near the geometry of row with gid = 5.

```sql
SELECT pgr_createVerticesTable('mytable','mygeom','src','tgt',rows_where:='the_geom && (SELECT st_buffer(mygeom,0.5) FROM mytable WHERE gid=5)');
SELECT pgr_createVerticesTable('mytable','src','mygeom','tgt',rows_where:='mygeom && (SELECT st_buffer(mygeom,0.5) FROM mytable WHERE gid=5)');
```

Selecting the rows where the geometry is near the geometry of the row with gid = 100 of the table `othertable`.

```sql
DROP TABLE IF EXISTS otherTable;
CREATE TABLE otherTable AS (SELECT 100 AS gid, st_point(2.5,2.5) AS other_geom);
SELECT pgr_createVerticesTable('mytable','mygeom','src','tgt',rows_where:='the_geom && (SELECT st_buffer(othergeom,0.5) FROM otherTable WHERE gid=100)');
SELECT pgr_createVerticesTable('mytable','src','mygeom','tgt',rows_where:='the_geom && (SELECT st_buffer(othergeom,0.5) FROM otherTable WHERE gid=100)');
```

Examples

```sql
SELECT pgr_createVerticesTable('edge_table');
```

```
NOTICE: PROCESSING:
NOTICE: pgr_createVerticesTable('edge_table','the_geom','source','target','true')
NOTICE: Performing checks, please wait ..... 
NOTICE: Populating public.edge_table_vertices_pgr, please wait...
NOTICE: ------> VERTICES TABLE CREATED WITH 17 VERTICES FOR 18 EDGES
```
The example uses the Sample Data network.

5.1.3 pgr_analyzeGraph

Name

pgr_analyzeGraph — Analyzes the network topology.

Synopsis

The function returns:

- OK after the analysis has finished.
- FAIL when the analysis was not completed due to an error.

```
  varchar pgr_analyzeGraph(text edge_table, double precision tolerance, 
                          text the_geom:='the_geom', text id:='id', 
                          text source:='source', text target:='target', text rows_where:='true')
```

Description

Prerequisites

The edge table to be analyzed must contain a source column and a target column filled with id’s of the vertices of the segments and the corresponding vertices table <edge_table>_vertices_pgr that stores the vertices information.

- Use pgr_createVerticesTable to create the vertices table.
- Use pgr_createTopology to create the topology and the vertices table.

Parameters

The analyze graph function accepts the following parameters:

- `edge_table` text: Network table name. (may contain the schema name as well)
- `tolerance` float8: Snapping tolerance of disconnected edges. (in projection unit)
the_geom  text  Geometry column name of the network table. Default value is the_geom.

id  text  Primary key column name of the network table. Default value is id.

source  text  Source column name of the network table. Default value is source.

target  text  Target column name of the network table. Default value is target.

rows_where  text  Condition to select a subset or rows. Default value is true to indicate all rows.

The function returns:

• OK after the analysis has finished.
  – Uses the vertices table: <edge_table>_vertices_pgr.
  – Fills completely the cnt and chk columns of the vertices table.
  – Returns the analysis of the section of the network defined by rows_where

• FAIL when the analysis was not completed due to an error.
  – The vertices table is not found.
  – A required column of the Network table is not found or is not of the appropriate type.
  – The condition is not well formed.
  – The names of source, target or id are the same.
  – The SRID of the geometry could not be determined.

The Vertices Table

The vertices table can be created with pgr_createVerticesTable or pgr_createTopology

The structure of the vertices table is:

  id  bigint  Identifier of the vertex.
  cnt  integer  Number of vertices in the edge_table that reference this vertex.
  chk  integer  Indicator that the vertex might have a problem.
  ein  integer  Number of vertices in the edge_table that reference this vertex as incoming. See pgr_analyzeOneway.
  eout  integer  Number of vertices in the edge_table that reference this vertex as outgoing. See pgr_analyzeOneway.
  the_geom  geometry  Point geometry of the vertex.

History

• New in version 2.0.0

Usage when the edge table’s columns MATCH the default values:

The simplest way to use pgr_analyzeGraph is:

```sql
SELECT  pgr_create_topology('edge_table',0.001);
SELECT  pgr_analyzeGraph('edge_table',0.001);
```
When the arguments are given in the order described in the parameters:

```sql
SELECT pgr_analyzeGraph('edge_table',0.001,'the_geom','id','source','target');
```

We get the same result as the simplest way to use the function.

**Warning:**

An error would occur when the arguments are not given in the appropriate order: In this example, the column `id` of the table `mytable` is passed to the function as the geometry column, and the geometry column `the_geom` is passed to the function as the id column.

```sql
SELECT pgr_analyzeGraph('edge_table',0.001,'id','the_geom','source','target');
```

ERROR: Can not determine the srid of the geometry "id" in table public.edge_table

When using the named notation

The order of the parameters do not matter:

```sql
SELECT pgr_analyzeGraph('edge_table',0.001,the_geom:='the_geom',id:='id',source:='source',target:='target');
```

```sql
SELECT pgr_analyzeGraph('edge_table',0.001,source:='source',id:='id',target:='target',the_geom:='the_geom');
```

Parameters defined with a default value can be omitted, as long as the value matches the default:

```sql
SELECT pgr_analyzeGraph('edge_table',0.001,source:='source');
```

Selecting rows using rows_where parameter

Selecting rows based on the id. Displays the analysis a the section of the network.

```sql
SELECT pgr_analyzeGraph('edge_table',0.001,rows_where:='id < 10');
```

Selecting the rows where the geometry is near the geometry of row with `id`=5.

```sql
SELECT pgr_analyzeGraph('edge_table',0.001,rows_where:='the_geom && (SELECT st_buffer(the_geom,0.05) FROM edge_table WHERE id=5)');
```

Selecting the rows where the geometry is near the geometry of the row with `gid`=100 of the table `othertable`.

```sql
DROP TABLE IF EXISTS otherTable;
CREATE TABLE otherTable AS (SELECT 100 AS gid, st_point(2.5,2.5) AS other_geom) ;
SELECT pgr_analyzeGraph('edge_table',0.001,rows_where:='the_geom && (SELECT st_buffer(other_geom,1) FROM otherTable WHERE gid=100)');
```

Usage when the edge table's columns DO NOT MATCH the default values:

For the following table

```sql
DROP TABLE IF EXISTS mytable;
CREATE TABLE mytable AS (SELECT id AS gid, source AS src ,target AS tgt , the_geom AS mygeom FROM edge_table);
SELECT pgr_createTopology('mytable',0.001,'mygeom','gid','src','tgt');
```

Using positional notation:

The arguments need to be given in the order described in the parameters:

```sql
SELECT pgr_analyzeGraph('mytable',0.001,'mygeom','gid','src','tgt');
```
Warning:
An error would occur when the arguments are not given in the appropriate order: In this example, the column gid of the table mytable is passed to the function as the geometry column, and the geometry column mygeom is passed to the function as the id column.

```sql
SELECT pgr_analyzeGraph('mytable', 0.001, 'gid', 'mygeom', 'src', 'tgt');
```

ERROR: Can not determine the srid of the geometry “gid” in table public.mytable

When using the named notation

The order of the parameters do not matter:

```sql
SELECT pgr_analyzeGraph('mytable', 0.001, the_geom:='mygeom', id:='gid', source:='src', target:='tgt');
```

```sql
SELECT pgr_analyzeGraph('mytable', 0.001, source:='src', id:='gid', target:='tgt', the_geom:='mygeom');
```

In this scenario omitting a parameter would create an error because the default values for the column names do not match the column names of the table.

Selecting rows using rows_where parameter

Selecting rows based on the id.

```sql
SELECT pgr_analyzeGraph('mytable', 0.001, 'mygeom', 'gid', 'src', 'tgt', rows_where:='gid < 10');
```

```sql
SELECT pgr_analyzeGraph('mytable', 0.001, source:='src', id:='gid', target:='tgt', the_geom:='mygeom', rows_where:='gid < 10');
```

Selecting the rows WHERE the geometry is near the geometry of row with id=5.

```sql
SELECT pgr_analyzeGraph('mytable', 0.001, 'mygeom', 'gid', 'src', 'tgt',
                      rows_where:='mygeom && (SELECT st_buffer(mygeom,1) FROM mytable WHERE gid=5)');
```

```sql
SELECT pgr_analyzeGraph('mytable', 0.001, source:='src', id:='gid', target:='tgt', the_geom:='mygeom',
                      rows_where:='mygeom && (SELECT st_buffer(mygeom,1) FROM mytable WHERE gid=5)');
```

Selecting the rows WHERE the geometry is near the place='myhouse' of the table otherTable. (note the use of quote_litera

```sql
DROP TABLE IF EXISTS otherTable;
CREATE TABLE otherTable AS (SELECT 'myhouse'::text AS place, st_point(2.5,2.5) AS other_geom);
SELECT pgr_analyzeGraph('mytable', 0.001, 'mygeom', 'gid', 'src', 'tgt',
                      rows_where:='mygeom && (SELECT st_buffer(other_geom,1) FROM otherTable WHERE place='||quote_literal('myhouse')||')');
```

```sql
SELECT pgr_analyzeGraph('mytable', 0.001, source:='src', id:='gid', target:='tgt', the_geom:='mygeom',
                      rows_where:='mygeom && (SELECT st_buffer(other_geom,1) FROM otherTable WHERE place='||quote_literal('myhouse')||')');
```

Examples

```sql
SELECT pgr_create_topology('edge_table', 0.001);
SELECT pgr_analyzeGraph('edge_table', 0.001);
```

5.1.4 pgr_analyzeOneway

Name

pgr_analyzeOneway — Analyzes oneway streets and identifies flipped segments.

Synopsis

This function analyzes oneway streets in a graph and identifies any flipped segments.

```sql
text pgr_analyzeOneway(geom_table text,
    text[] s_in_rules, text[] s_out_rules,
    text[] t_in_rules, text[] t_out_rules,
    text oneway='oneway', text source='source', text target='target',
    boolean two_way_if_null=true);
```

Description

The analyses of one way segments is pretty simple but can be a powerful tools to identifying some the potential problems created by setting the direction of a segment the wrong way. A node is a source if it has edges the exit from that node and no edges enter that node. Conversely, a node is a sink if all edges enter the node but none exit that node. For a source type node it is logically impossible to exist because no vehicle can exit the node if no vehicle and enter the node. Likewise, if you had a sink node you would have an infinite number of vehicle piling up on this node because you can enter it but not leave it.

So why do we care if the are not feasible? Well if the direction of an edge was reversed by mistake we could generate exactly these conditions. Think about a divided highway and on the north bound lane one segment got entered wrong or maybe a sequence of multiple segments got entered wrong or maybe this happened on a round-about. The result would be potentially a source and/or a sink node.

So by counting the number of edges entering and exiting each node we can identify both source and sink nodes so that you can look at those areas of your network to make repairs and/or report the problem back to your data vendor.

Prerequisites

The edge table to be analyzed must contain a source column and a target column filled with id’s of the vertices of the segments and the corresponding vertices table edge_table>.vertices_pgr that stores the vertices information.

- Use `pgr_createVerticesTable` to create the vertices table.
- Use `pgr_createTopology` to create the topology and the vertices table.

Parameters

- `edge_table` text: Network table name. (may contain the schema name as well)
- `s_in_rules` text[]: source node in rules
- `s_out_rules` text[]: source node out rules
- `t_in_rules` text[]: target node in rules
- `t_out_rules` text[]: target node out rules
- `oneway` text: oneway column name name of the network table. Default value is oneway.
- `source` text: Source column name of the network table. Default value is source.
- `target` text: Target column name of the network table. Default value is target.
two_way_if_null boolean flag to treat oneway NULL values as bi-directional. Default value is true.

Note: It is strongly recommended to use the named notation. See pgr_createVerticesTable or pgr_createTopology for examples.

The function returns:
- OK after the analysis has finished.
  - Uses the vertices table: <edge_table>_vertices_pgr.
  - Fills completely the ein and eout columns of the vertices table.
- FAIL when the analysis was not completed due to an error.
  - The vertices table is not found.
  - A required column of the Network table is not found or is not of the appropriate type.
  - The names of source, target or oneway are the same.

The rules are defined as an array of text strings that if match the oneway value would be counted as true for the source or target in or out condition.

The Vertices Table

The vertices table can be created with pgr_createVerticesTable or pgr_createTopology

The structure of the vertices table is:
- id bigint Identifier of the vertex.
- cnt integer Number of vertices in the edge_table that reference this vertex. See pgr_analyzeGraph.
- chk integer Indicator that the vertex might have a problem. See pgr_analyzeGraph.
- ein integer Number of vertices in the edge_table that reference this vertex as incoming.
- eout integer Number of vertices in the edge_table that reference this vertex as outgoing.
- the_geom geometry Point geometry of the vertex.

History

- New in version 2.0.0

Examples

```sql
SELECT pgr_analyzeOneway('edge_table',
ARRAY['', 'B', 'TF'],
ARRAY['', 'B', 'FT'],
ARRAY['', 'B', 'FT'],
ARRAY['', 'B', 'TF'],
oneway:='dir');
NOTICE: PROCESSING:
NOTICE: pgr_analyzeGraph('edge_table','{"",B,TF}','{"",B,FT}','{"",B,FT}','{"",B,TF}','dir','source','target',t)
NOTICE: Analyzing graph for one way street errors.
NOTICE: Analysis 25% complete ...
NOTICE: Analysis 50% complete ...
NOTICE: Analysis 75% complete ...
NOTICE: Analysis 100% complete ...
NOTICE: Found 0 potential problems in directionality
```
The queries use the Sample Data network.

5.1.5 pgr_nodeNetwork

Name

pgr_nodeNetwork - Nodes an network edge table.

Author Nicolas Ribot

Copyright Nicolas Ribot, The source code is released under the MIT-X license.

Synopsis

The function reads edges from a not “noded” network table and writes the “noded” edges into a new table.

```
text pgr_nodenetwork(text edge_table, float8, tolerance, text id='id', text the_geom='the_geom', text table_ending='noded')
```

Description

A common problem associated with bringing GIS data into pgRouting is the fact that the data is often not “noded” correctly. This will create invalid topologies, which will result in routes that are incorrect.

What we mean by “noded” is that at every intersection in the road network all the edges will be broken into separate road segments. There are cases like an over-pass and under-pass intersection where you can not traverse from the over-pass to the under-pass, but this function does not have the ability to detect and accommodate those situations.

This function reads the edge_table table, that has a primary key column id and geometry column named the_geom and intersect all the segments in it against all the other segments and then creates a table edge_table_noded. It uses the tolerance for deciding that multiple nodes within the tolerance are considered the same node.

Parameters

- edge_table text Network table name. (may contain the schema name as well)
- tolerance float8 tolerance for coincident points (in projection unit)dd
- id text Primary key column name of the network table. Default value is id.
- the_geom text Geometry column name of the network table. Default value is the_geom.
- table_ending text Suffix for the new table’s. Default value is noded.

The output table will have for edge_table_noded
id  bigint  Unique identifier for the table
old_id  bigint  Identifier of the edge in original table
sub_id  integer  Segment number of the original edge
source  integer  Empty source column to be used with pgr_createTopology function
target  integer  Empty target column to be used with pgr_createTopology function
the_geom  geometry  Geometry column of the noded network

History

- New in version 2.0.0

Example

Let’s create the topology for the data in Sample Data

```
SELECT pgr_createTopology('edge_table', 0.001);
```

```
NOTICE: PROCESSING:
NOTICE: pgr_createTopology('edge_table',0.001,'the_geom','id','source','target','true')
NOTICE: Performing checks, please wait ...
NOTICE: Creating Topology, please wait...
NOTICE: --------------> TOPOLOGY CREATED FOR 18 edges
NOTICE: Rows with NULL geometry or NULL id: 0
NOTICE: Vertices table for table public.edge_table is: public.edge_table_vertices_pgr
NOTICE: ---------------------------------------------
```

pgr_createtopology
--------------------
OK
(1 row)

Now we can analyze the network.

```
SELECT pgr_analyzeGraph('edge_table', 0.001);
```

```
NOTICE: PROCESSING:
NOTICE: pgr_analyzeGraph('edge_table',0.001,'the_geom','id','source','target','true')
NOTICE: Performing checks, please wait...
NOTICE: Analyzing for dead ends. Please wait...
NOTICE: Analyzing for gaps. Please wait...
NOTICE: Analyzing for isolated edges. Please wait...
NOTICE: Analyzing for ring geometries. Please wait...
NOTICE: Analyzing for intersections. Please wait...
NOTICE: ANALYSIS RESULTS FOR SELECTED EDGES:
NOTICE: Isolated segments: 2
NOTICE: Dead ends: 7
NOTICE: Potential gaps found near dead ends: 1
NOTICE: Intersections detected: 1
NOTICE: Ring geometries: 0
```

pgr_analyzeGraph
------------------
OK
(1 row)

The analysis tell us that the network has a gap and an intersection. We try to fix the problem using:

```
SELECT pgr_nodeNetwork('edge_table', 0.001);
```

```
NOTICE: PROCESSING:
NOTICE: pgr_nodeNetwork('edge_table',0.001,'the_geom','id','noded')
NOTICE: Performing checks, please wait ...
```

```
NOTICE: Processing, please wait ...
```

56 Chapter 5. Topology functions
Inspecting the generated table, we can see that edges 13, 14 and 18 have been segmented.

```sql
SELECT old_id, sub_id FROM edge_table_noded ORDER BY old_id, sub_id;
```

```
<table>
<thead>
<tr>
<th>old_id</th>
<th>sub_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>1</td>
</tr>
<tr>
<td>8</td>
<td>1</td>
</tr>
<tr>
<td>9</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>1</td>
</tr>
<tr>
<td>11</td>
<td>1</td>
</tr>
<tr>
<td>12</td>
<td>1</td>
</tr>
<tr>
<td>13</td>
<td>1</td>
</tr>
<tr>
<td>13</td>
<td>2</td>
</tr>
<tr>
<td>14</td>
<td>1</td>
</tr>
<tr>
<td>14</td>
<td>2</td>
</tr>
<tr>
<td>15</td>
<td>1</td>
</tr>
<tr>
<td>16</td>
<td>1</td>
</tr>
<tr>
<td>17</td>
<td>1</td>
</tr>
<tr>
<td>18</td>
<td>1</td>
</tr>
<tr>
<td>18</td>
<td>2</td>
</tr>
</tbody>
</table>
```

We can create the topology of the new network.

```sql
SELECT pgr_createTopology('edge_table_noded', 0.001);
```

Now let’s analyze the new topology.

```sql
SELECT pgr_analyzeGraph('edge_table_noded', 0.001);
```

Images

Before Image
Comparing the results

Comparing with the Analysis in the original edge_table, we see that.

<table>
<thead>
<tr>
<th></th>
<th>Before</th>
<th>After</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table name</td>
<td>edge_table</td>
<td>edge_table_noded</td>
</tr>
<tr>
<td>Fields</td>
<td>All original fields</td>
<td>Has only basic fields to do a topology analysis</td>
</tr>
<tr>
<td>Dead ends</td>
<td>• Edges with 1 dead end: 1,6,24</td>
<td>Edges with 1 dead end: 1-1,6-1,14-2,18-1,17-1,18-2</td>
</tr>
<tr>
<td></td>
<td>• Edges with 2 dead ends 17,18</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Edge 17’s right node is a dead end</td>
<td></td>
</tr>
<tr>
<td></td>
<td>because there is no other edge</td>
<td></td>
</tr>
<tr>
<td></td>
<td>sharing that same node. (cnt=1)</td>
<td></td>
</tr>
<tr>
<td>Isolated segments</td>
<td>two isolated segments: 17 and 18</td>
<td>No Isolated segments</td>
</tr>
<tr>
<td></td>
<td>both they have 2 dead ends</td>
<td>• Edge 17 now shares a node with edges 14-1 and</td>
</tr>
<tr>
<td></td>
<td></td>
<td>14-2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Edges 18-1 and 18-2 share a node with edges</td>
</tr>
<tr>
<td></td>
<td></td>
<td>13-1 and 13-2</td>
</tr>
<tr>
<td>Gaps</td>
<td>There is a gap between edge 17 and</td>
<td>Edge 14 was segmented Now edges: 14-1 14-2 17</td>
</tr>
<tr>
<td></td>
<td>14 because edge 14 is near to the</td>
<td>share the same node</td>
</tr>
<tr>
<td></td>
<td>right node of edge 17</td>
<td>The tolerance value was taken in account</td>
</tr>
<tr>
<td>Intersections</td>
<td>Edges 13 and 18 were intersecting</td>
<td>Edges were segmented. So, now in the intersection’s point there is a node and the following edges share it: 13-1 13-2 18-1 18-2</td>
</tr>
</tbody>
</table>

5.1. Topology Functions 59
Now, we are going to include the segments 13-1, 13-2 14-1, 14-2,18-1 and 18-2 into our edge-table, copying the data for dir,cost,and reverse cost with the following steps:

- Add a column old_id into edge_table, this column is going to keep track the id of the original edge
- Insert only the segmented edges, that is, the ones whose max(sub_id) > 1

```sql
alter table edge_table drop column if exists old_id;
alter table edge_table add column old_id integer;
insert into edge_table (old_id,dir,cost,reverse_cost,the_geom)
(with
    segmented as (select old_id,count(*) as i from edge_table_noded group by old_id)
select segments.old_id,dir,cost,reverse_cost,segments.the_geom
from edge_table as edges join edge_table_noded as segments
on (edges.id = segments.old_id)
where edges.id in (select old_id from segmented where i>1) );
```

We recreate the topology:

```sql
SELECT pgr_createTopology('edge_table', 0.001);
```

```
NOTICE: PROCESSING:
NOTICE: pgr_createTopology('edge_table',0.001,'the_geom','id','source','target','true')
NOTICE: Performing checks, please wait ....
NOTICE: Creating Topology, Please wait....
NOTICE: ----------> TOPOLOGY CREATED FOR 24 edges
NOTICE: Vertices table for table public.edge_table is: public.edge_table_vertices_pgr
OK
(1 row)
```

To get the same analysis results as the topology of edge_table_noded, we do the following query:

```sql
SELECT pgr_analyzeGraph('edge_table', 0.001,rows_where:='id not in (select old_id from edge_table where old_id is not null)');
```

```
NOTICE: PROCESSING:
NOTICE: pgr_analyzeGraph('edge_table',0.001,'the_geom','id','source','target','id not in (select old_id from edge_table where old_id is not null)')
NOTICE: Performing checks, please wait...
NOTICE: Analyzing for dead ends. Please wait...
NOTICE: Analyzing for isolated edges. Please wait...
NOTICE: Analyzing for intersections. Please wait...
NOTICE: ANALYSIS RESULTS FOR SELECTED EDGES:
NOTICE: Isolated segments: 0
NOTICE: Dead ends: 6
NOTICE: Potential gaps found near dead ends: 0
NOTICE: Intersections detected: 0
NOTICE: Ring geometries: 0
OK
(1 row)
```

To get the same analysis results as the original edge_table, we do the following query:

```sql
SELECT pgr_analyzeGraph('edge_table', 0.001,rows_where:='old_id is null');
```

```
NOTICE: PROCESSING:
NOTICE: pgr_analyzeGraph('edge_table',0.001,'the_geom','id','source','target','old_id is null')
NOTICE: Performing checks, please wait...
NOTICE: Analyzing for dead ends. Please wait...
OK
(1 row)
```
Or we can analyze everything because, maybe edge 18 is an overpass, edge 14 is an under pass and there is also a street level juction, and the same happens with edges 17 and 13.

```
SELECT pgr_analyzeGraph('edge_table', 0.001);
```

6.1.1 pgr_apspJohnson - All Pairs Shortest Path, Johnson’s Algorithm

Name

pgr_apspJohnson - Returns all costs for each pair of nodes in the graph.

Synopsis

Johnson’s algorithm is a way to find the shortest paths between all pairs of vertices in a sparse, edge weighted, directed graph. Returns a set of `pgr_costResult` (seq, id1, id2, cost) rows for every pair of nodes in the graph.

```sql
pgr_costResult[] pgr_apspJohnson(sql text);
```

Description

- `sql` a SQL query that should return the edges for the graph that will be analyzed:
  ```sql
  SELECT source, target, cost FROM edge_table;
  ```
  - `source` int4 identifier of the source vertex for this edge
  - `target` int4 identifier of the target vertex for this edge
  - `cost` float8 a positive value for the cost to traverse this edge

Returns set of `pgr_costResult[]`:

- `seq` row sequence
- `id1` source node ID
- `id2` target node ID
- `cost` cost to traverse from id1 to id2

History

- New in version 2.0.0

Examples

```sql
SELECT seq, id1 AS from, id2 AS to, cost
FROM pgr_apspJohnson(
  'SELECT source, target, cost FROM edge_table'
);
```

<table>
<thead>
<tr>
<th>seq</th>
<th>from</th>

### 6.1.2 pgr_apspWarshall - All Pairs Shortest Path, Floyd-Warshall Algorithm

**Name**

`pgr_apspWarshall` - Returns all costs for each pair of nodes in the graph.

**Synopsis**

The Floyd-Warshall algorithm (also known as Floyd’s algorithm and other names) is a graph analysis algorithm for finding the shortest paths between all pairs of nodes in a weighted graph. Returns a set of `pgr_costResult` (seq, id1, id2, cost) rows for every pair of nodes in the graph.

```
| pgr_costResult[] | pgr_apspWarshall(sql text, directed boolean, reverse_cost boolean); |
```

**Description**

- `sql` a SQL query that should return the edges for the graph that will be analyzed:

  ```sql
  SELECT id, source, target, cost FROM edge_table;
  ```

  - `id` int4 identifier of the edge
  - `source` int4 identifier of the source vertex for this edge
  - `target` int4 identifier of the target vertex for this edge
  - `cost` float8 a positive value for the cost to traverse this edge

- `directed` true if the graph is directed
- `reverse_cost` if true, the `reverse_cost` column of the SQL generated set of rows will be used for the cost of the traversal of the edge in the opposite direction.

**Returns set of pgr_costResult[]:**

- `seq` row sequence
- `id1` source node ID
- `id2` target node ID
- `cost` cost to traverse from `id1` to `id2`

**History**

- New in version 2.0.0

**Examples**
SELECT seq, id1 AS from, id2 AS to, cost
FROM pgr_apspWarshall(
    'SELECT id, source, target, cost FROM edge_table',
    false, false
);

<table>
<thead>
<tr>
<th>seq</th>
<th>from</th>
<th>to</th>
<th>cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>3</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>4</td>
<td>-1</td>
</tr>
</tbody>
</table>

The query uses the Sample Data network.

See Also

- `pgr_costResult[]`
- `pgr_apspJohnson - All Pairs Shortest Path, Johnson’s Algorithm`

### 6.1.3 pgr_astar - Shortest Path A*

#### Name

pgr_astar — Returns the shortest path using A* algorithm.

#### Synopsis

The A* (pronounced “A Star”) algorithm is based on Dijkstra’s algorithm with a heuristic that allow it to solve most shortest path problems by evaluation only a sub-set of the overall graph. Returns a set of `pgr_costResult[]` (seq, id1, id2, cost) rows, that make up a path.

```
pgr_costResult[] pgr_astar(sql text, source integer, target integer,
                          directed boolean, has_rcost boolean);
```

#### Description

- **sql** a SQL query, which should return a set of rows with the following columns:

  ```
  SELECT id, source, target, cost, x1, y1, x2, y2 [,reverse_cost] FROM edge_table
  ```

  - **id** int4 identifier of the edge
  - **source** int4 identifier of the source vertex
  - **target** int4 identifier of the target vertex
  - **cost** float8 value, of the edge traversal cost. A negative cost will prevent the edge from being inserted in the graph.
  - **x1** x coordinate of the start point of the edge
  - **y1** y coordinate of the start point of the edge
  - **x2** x coordinate of the end point of the edge
  - **y2** y coordinate of the end point of the edge
**reverse_cost** (optional) the cost for the reverse traversal of the edge. This is only used when the **directed** and **has_rcost** parameters are **true** (see the above remark about negative costs).

**source** int4 id of the start point

**target** int4 id of the end point

**directed** true if the graph is directed

**has_rcost** if **true**, the **reverse_cost** column of the SQL generated set of rows will be used for the cost of the traversal of the edge in the opposite direction.

Returns set of **pgr_costResult[]**:

<table>
<thead>
<tr>
<th>seq</th>
<th>id1</th>
<th>id2</th>
<th>cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>16</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>9</td>
<td>9</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
<td>8</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>5</td>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>-1</td>
<td>0</td>
</tr>
</tbody>
</table>

(6 rows)

**Examples**

- Without **reverse_cost**

```sql
SELECT seq, id1 AS node, id2 AS edge, cost
FROM pgr_astar(
    'SELECT id, source, target, cost, x1, y1, x2, y2 FROM edge_table',
    4, 1, false, false
);
```

<table>
<thead>
<tr>
<th>seq</th>
<th>node</th>
<th>edge</th>
<th>cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>16</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>9</td>
<td>9</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
<td>8</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>5</td>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>-1</td>
<td>0</td>
</tr>
</tbody>
</table>

(6 rows)

- With **reverse_cost**

```sql
SELECT seq, id1 AS node, id2 AS edge, cost
FROM pgr_astar(
    'SELECT id, source, target, cost, x1, y1, x2, y2, reverse_cost FROM edge_table',
    4, 1, true, true
);
```

<table>
<thead>
<tr>
<th>seq</th>
<th>node</th>
<th>edge</th>
<th>cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>-1</td>
<td>0</td>
</tr>
</tbody>
</table>

(4 rows)

The queries use the **Sample Data** network.

---

6.1. Routing Functions 67
6.1.4 pgr_bdAstar - Bi-directional A* Shortest Path

Name

pgr_bdAstar - Returns the shortest path using Bidirectional A* algorithm.

Synopsis

This is a bi-directional A* search algorithm. It searches from the source toward the destination and at the same time from the destination to the source and terminates when these two searches meet in the middle. Returns a set of pgr_costResult (seq, id1, id2, cost) rows, that make up a path.

```
pgr_costResult[] pgr_bdAstar(sql text, source integer, target integer, directed boolean, has_rcost boolean);
```

Description

**sql** a SQL query, which should return a set of rows with the following columns:

```
SELECT id, source, target, cost, x1, y1, x2, y2 [,reverse_cost] FROM edge_table
```

- **id** int4 identifier of the edge
- **source** int4 identifier of the source vertex
- **target** int4 identifier of the target vertex
- **cost** float8 value, of the edge traversal cost. A negative cost will prevent the edge from being inserted in the graph.
- **x1** x coordinate of the start point of the edge
- **y1** y coordinate of the start point of the edge
- **x2** x coordinate of the end point of the edge
- **y2** y coordinate of the end point of the edge
- **reverse_cost** (optional) the cost for the reverse traversal of the edge. This is only used when the directed and has_rcost parameters are true (see the above remark about negative costs).

- **source** int4 id of the start point
- **target** int4 id of the end point
- **directed** true if the graph is directed
- **has_rcost** if true, the reverse_cost column of the SQL generated set of rows will be used for the cost of the traversal of the edge in the opposite direction.

Returns set of pgr_costResult[]:

- **seq** row sequence
- **id1** node ID
- **id2** edge ID (−1 for the last row)
**cost**  cost to traverse from id1 using id2

**Warning:** You must reconnect to the database after CREATE EXTENSION pgrouting. Otherwise the function will return Error computing path: std::bad_alloc.

**History**

- New in version 2.0.0

**Examples**

- **Without reverse_cost**

```sql
SELECT seq, id1 AS node, id2 AS edge, cost
FROM pgr_bdAstar(
    'SELECT id, source, target, cost, x1, y1, x2, y2 FROM edge_table',
    4, 10, false, false
);
```

<table>
<thead>
<tr>
<th>seq</th>
<th>node</th>
<th>edge</th>

6.1.5 pgr_bdDijkstra - Bi-directional Dijkstra Shortest Path

Name

pgr_bdDijkstra - Returns the shortest path using Bidirectional Dijkstra algorithm.

Synopsis

This is a bi-directional Dijkstra search algorithm. It searches from the source toward the destination and at the same time from the destination to the source and terminates when these two searches meet in the middle. Returns a set of pgr_costResult (seq, id1, id2, cost) rows, that make up a path.

\[
pgr\_costResult[]\ pgr\_bdDijkstra(\text{sql text}, \text{source integer}, \text{target integer}, \\
\text{directed boolean, has\_rcost boolean});
\]

Description

sql a SQL query, which should return a set of rows with the following columns:

\[
\text{SELECT id, source, target, cost [,reverse\_cost] FROM edge_table}
\]

- \text{id int4 identifier of the edge}
- \text{source int4 identifier of the source vertex}
- \text{target int4 identifier of the target vertex}
- \text{cost float8 value, of the edge traversal cost. A negative cost will prevent the edge from being inserted in the graph.}
- \text{reverse\_cost (optional) the cost for the reverse traversal of the edge. This is only used when the directed and has\_rcost parameters are true (see the above remark about negative costs).}

- \text{source int4 id of the start point}
- \text{target int4 id of the end point}
- \text{directed true if the graph is directed}
- \text{has\_rcost if true, the reverse\_cost column of the SQL generated set of rows will be used for the cost of the traversal of the edge in the opposite direction.}

Returns set of pgr_costResult[]:

- \text{seq row sequence}
- \text{id1 node ID}
- \text{id2 edge ID (-1 for the last row)}
- \text{cost cost to traverse from id1 using id2}

History

- New in version 2.0.0

Examples

- Without reverse\_cost
SELECT seq, id1 AS node, id2 AS edge, cost 
FROM pgr_bdDijkstra(
    'SELECT id, source, target, cost FROM edge_table',
    4, 10, false, false
);

6.1.6 pgr_dijkstra - Shortest Path Dijkstra

Version 2.0 (deprecated)

- pgr_dijkstra - Shortest Path Dijkstra

Version 2.1

- pgr_dijkstra - Shortest Path Dijkstra

6.1.7 The problem definition

Given the following query:
pgr_dijkstra(sql, start_vid, end_vid, directed)
where \( sql = \{ (id_i, source_i, target_i, cost_i, reverse\_cost_i) \} \)

and

- \( source = \bigcup source_i \),
- \( target = \bigcup target_i \).

The graphs are defined as follows:

### Directed graph

The weighted directed graph, \( G_d(V, E) \), is defined by:

- the set of vertices \( V \)
  \( V = source \cup target \cup start\_vid \cup end\_vid \)
- the set of edges \( E \)
  \[
  E = \begin{cases} 
  \{ (source_i, target_i, cost_i) \text{ when } cost > 0 \} 
  & \text{if } reverse\_cost = \text{true} \\
  \{ (source_i, target_i, cost_i) \text{ when } cost > 0 \} 
  \cup 
  \{ (target_i, source_i, reverse\_cost_i) \text{ when } reverse\_cost_i > 0 \} 
  & \text{if } reverse\_cost \neq \text{true} 
  \end{cases}
  \]

### Undirected graph

The weighted undirected graph, \( G_u(V, E) \), is defined by:

- the set of vertices \( V \)
  \( V = source \cup target \cup start\_vid \cup end\_vid \)
- the set of edges \( E \)
  \[
  E = \begin{cases} 
  \{ (source_i, target_i, cost_i) \text{ when } cost > 0 \} 
  \cup 
  \{ (target_i, source_i, cost_i) \text{ when } cost > 0 \} 
  & \text{if } reverse\_cost = \text{true} \\
  \{ (source_i, target_i, cost_i) \text{ when } cost > 0 \} 
  \cup 
  \{ (target_i, source_i, cost_i) \text{ when } cost > 0 \} 
  \cup 
  \{ (target_i, source_i, reverse\_cost_i) \text{ when } reverse\_cost_i > 0 \} 
  \cup 
  \{ (source_i, target_i, reverse\_cost_i) \text{ when } reverse\_cost_i > 0 \} 
  & \text{if } reverse\_cost \neq \text{true} 
  \end{cases}
  \]

### The problem

Given:

- \( start\_vid \in V \) a starting vertex
- \( end\_vid \in V \) an ending vertex

\[
G(V, E) = \begin{cases} 
  G_d(V, E) & \text{if } directed = \text{true} \\
  G_u(V, E) & \text{if } directed = \text{false} 
  \end{cases}
\]
Then:

\[
pgr\_dijkstra(sql, start\_vid, end\_vid, directed) = \begin{cases} \text{shortest path } \pi \text{ between } start\_vid \text{ and } end\_vid & \text{if } \exists \pi \\ \text{otherwise} \end{cases}
\]

\[
\pi = \{(path_i, node_i, edge_i, cost_i, agg\_cost_i)\}
\]

where:

- \(path_i = i\)
- \(path_{|\pi|} = |\pi|\)
- \(node_i \in V\)
- \(node_1 = start\_vid\)
- \(node_{|\pi|} = end\_vid\)
- \(\forall i \neq |\pi|, (node_i, node_{i+1}, cost_i) \in E\)
- \(edge_i = \begin{cases} id_{(node_i, node_{i+1}, cost_i)} & \text{when } i \neq |\pi| \\ -1 & \text{when } i = |\pi| \end{cases}\)
- \(cost_i = cost_{(node_i, node_{i+1})}\)
- \(agg\_cost_i = \begin{cases} 0 & \text{when } i = 1 \\ \sum_{k=1}^{i} cost_{(node_{k-1}, node_k)} & \text{when } i \neq 1 \end{cases}\)

In other words: The algorithm returns a the shortest path between \(start\_vid\) and \(end\_vid\), if it exists, in terms of a sequence of nodes and edges.

- \(path\) indicates the relative position in the path of the \(node\) or \(edge\).
- \(cost\) is the cost of the edge to be used to go to the next node.
- \(agg\_cost\) is the cost from the \(start\_vid\) up to the node.

If there is no path, the resulting set is empty.

**pgr_dijkstra (V 2.0)- Shortest Path Dijkstra**

**Name**

pgr_dijkstra — Returns the shortest path using Dijkstra algorithm.

**Synopsis**

Dijkstra’s algorithm, conceived by Dutch computer scientist Edsger Dijkstra in 1956. It is a graph search algorithm that solves the single-source shortest path problem for a graph with non-negative edge path costs, producing a shortest path tree. Returns a set of `pgr_costResult` (seq, id1, id2, cost) rows, that make up a path.

| pgr_costResult[] | pgr_dijkstra(sql, integer source, integer target, boolean directed, boolean has_rcost); |

**Warning:** This signature is being deprecated in version 2.1, Please use it without the has_rcost flag instead:

pgr_dijkstra(sql, source, target, directed)

See **pgr_dijkstra - Shortest Path Dijkstra**

---

6.1. Routing Functions 73
Description

sql a SQL query, which should return a set of rows with the following columns:

```sql
SELECT id, source, target, cost [,reverse_cost] FROM edge_table
```

- **id** int4 identifier of the edge
- **source** int4 identifier of the source vertex
- **target** int4 identifier of the target vertex
- **cost** float8 value, of the edge traversal cost. A negative cost will prevent the edge from being inserted in the graph.
- **reverse_cost** float8 (optional) the cost for the reverse traversal of the edge. This is only used when the **directed** and **has_rcost** parameters are true (see the above remark about negative costs).

- **source** int4 id of the start point
- **target** int4 id of the end point
- **directed** true if the graph is directed
- **has_rcost** if true, the **reverse_cost** column of the SQL generated set of rows will be used for the cost of the traversal of the edge in the opposite direction.

Returns set of **pgr_costResult[]**:

- **seq** row sequence
- **id1** node ID
- **id2** edge ID (−1 for the last row)
- **cost** cost to traverse from id1 using id2

History

- Renamed in version 2.0.0

Examples: Directed

- Without **reverse_cost**

```sql
SELECT seq, id1 AS node, id2 AS edge, cost
FROM pgr_dijkstra(
    'SELECT id, source, target, cost, reverse_cost FROM edge_table',
    2, 3, true, false
);
```

<table>

`pgr_dijkstra` - Shortest Path Dijkstra

`pgr_dijkstra` — Returns the shortest path(s) using Dijkstra algorithm. In particular, the Dijkstra algorithm implemented by Boost Graph.

Fig. 6.1: Boost Graph Inside
Synopsis

Dijkstra’s algorithm, conceived by Dutch computer scientist Edsger Dijkstra in 1956. It is a graph search algorithm that solves the shortest path problem for a graph with non-negative edge path costs, producing a shortest path from a starting vertex (start_vid) to an ending vertex (end_vid). This implementation can be used with a directed graph and an undirected graph.

Signatures

Minimal signature

The minimal signature is for a directed graph from one start_vid to one end_vid:

\[
pgr_dijkstra(text\,\,\,edges\_sql,\,\,bigint\,\,start\_vid,\,\,bigint\,\,end\_vid)
\]

\[
RETURNS\,SET\,OF\,\,(seq,\,path\_seq,\,node,\,edge,\,cost,\,agg\_cost)\,or\,EMPTY\,SET
\]

Dijkstra 1 to 1

This signature performs a Dijkstra from one start_vid to one end_vid:

- on a directed graph when directed flag is missing or is set to true.
- on an undirected graph when directed flag is set to false.

\[
pgr_dijkstra(text\,\,edges\_sql,\,bigint\,\,start\_vid,\,bigint\,\,end\_vid,\,boolean\,\,directed:=true);
\]

\[
RETURNS\,SET\,OF\,\,(seq,\,path\_seq,\,node,\,edge,\,cost,\,agg\_cost)\,or\,EMPTY\,SET
\]

Dijkstra many to 1:

\[
pgr_dijkstra(text\,\,edges\_sql,\,array[ANY\_INTEGER]\,\,\,start\_vids,\,bigint\,\,end\_vid,\,boolean\,\,directed:=true);
\]

\[
RETURNS\,SET\,OF\,\,(seq,\,path\_seq,\,start\_vid,\,node,\,edge,\,cost,\,agg\_cost)\,or\,EMPTY\,SET
\]

This signature performs a Dijkstra from each start_vid in start_vids to one end_vid:

- on a directed graph when directed flag is missing or is set to true.
- on an undirected graph when directed flag is set to false.

Using this signature, will load once the graph and perform several one to one Dijkstra where the ending vertex is fixed. The result is the union of the results of the one to one dijkstra.

The extra start_vid in the result is used to distinguish to which path it belongs.

Dijkstra 1 to many:

\[
pgr_dijkstra(text\,\,edges\_sql,\,bigint\,\,start\_vid,\,array[ANY\_INTEGER]\,\,\,end\_vids,\,boolean\,\,directed:=true);
\]

\[
RETURNS\,SET\,OF\,\,(seq,\,path\_seq,\,end\_vid,\,node,\,edge,\,cost,\,agg\_cost)\,or\,EMPTY\,SET
\]

This signature performs a Dijkstra from one start_vid to each end_vid in end_vids:

- on a directed graph when directed flag is missing or is set to true.
- on an undirected graph when directed flag is set to false.
Using this signature, will load once the graph and perform several 1 to 1 Dijkstra where the starting vertex is fixed. The result is the union of the results of the one to one dijkstra.

The extra end_vid in the result is used to distinguish to which path it belongs.

**Dijkstra many to many:**

```sql
pgr_dijkstra(text edges_sql, array[ANY_INTEGER] start vids, array[ANY_INTEGER] end vids, 
            boolean directed:=true);
```

Returns set of (seq, path_seq, start_vid, end_vid, node, edge, cost, agg_cost) or EMPTY SET

This signature performs a Dijkstra from each start_vid in start_vids to each end_vid in end_vids:

- on a directed graph when directed flag is missing or is set to true.
- on an undirected graph when directed flag is set to false.

Using this signature, will load once the graph and perform all combinations for starting vertices and ending vertices.

The extra start_vid and end_vid in the result is used to distinguish to which path it belongs.

### Description of the Signatures

#### Description of the SQL query

**edges_sql** an SQL query, which should return a set of rows with the following columns:

- **id** ANY-INTEGER identifier of the edge.
- **source** ANY-INTEGER identifier of the first end point vertex of the edge.
- **target** ANY-INTEGER identifier of the second end point vertex of the edge.
- **cost** ANY-NUMERICAL weight of the edge (source, target), if negative: edge (source, target) does not exist, therefore it’s not part of the graph.
- **reverse_cost** ANY-NUMERICAL (optional) weight of the edge (target, source), if negative: edge (target, source) does not exist, therefore it’s not part of the graph.

Where:

- ANY-INTEGER smallint, int, bigint
- ANY-NUMERICAL smallint, int, bigint, real, float

For example:

```sql
SELECT id, source, target, cost, reverse_cost from edge_table where geom && ST_Expand(ST_SetSRID(ST_Point(45, 34), 4326), 0.1)
```

### Description of the parameters of the signatures

- **sql** SQL query as described above.
- **start_vid** BIGINT identifier of the starting vertex of the path.
- **start_vids** array[ANY-INTEGER] array of identifiers of starting vertices.
- **end_vid** BIGINT identifier of the ending vertex of the path.
- **end_vids** array[ANY-INTEGER] array of identifiers of ending vertices.
- **directed** boolean (optional). When false the graph is considered as Undirected. Default is true which considers the graph as Directed.
Description of the return values

Returns set of \( \{ \text{seq} \ [, \ \text{start_vid}] \ [, \ \text{end_vid}] \ , \ \text{node} , \ \text{edge} , \ \text{cost} , \ \text{agg_cost} \} \)

### seq
INT is a sequential value starting from 1.

### path_seq
INT relative position in the path. Has value 1 for the beginning of a path.

### start_vid
BIGINT id of the starting vertex. Used when multiple starting vertices are in the query.

### end_vid
BIGINT id of the ending vertex. Used when multiple ending vertices are in the query.

### node
BIGINT id of the node in the path from start_vid to end_v.

### edge
BIGINT id of the edge used to go from node to the next node in the path sequence. -1 for the last node of the path.

### cost
FLOAT cost to traverse from node using edge to the next node in the path sequence.

### agg_cost
FLOAT total cost from start_v to node.

 Examples

The examples of this section are based on the Sample Data network.

The examples include combinations from starting vertices 2 and 11 to ending vertices 3 and 5 in a directed and undirected graph with and with out reverse_cost.

#### Examples for queries marked as directed with cost and reverse_cost columns

The examples in this section use the following Graph 1: Directed, with cost and reverse cost

```sql
SELECT * FROM pgr_dijkstra(
    'SELECT id, source, target, cost, reverse_cost FROM edge_table',
    2, 3
);
```

```
seq | path_seq | node | edge | cost | agg_cost
-----+----------+------+------+------+----------
 1 | 1 | 2 | 4 | 1 | 0
 2 | 2 | 5 | 8 | 1 | 1
 3 | 3 | 6 | 9 | 1 | 2
 4 | 4 | 9 | 16 | 1 | 3
 5 | 5 | 4 | 3 | 1 | 4
 6 | 6 | 3 | -1 | 0 | 5
(6 rows)
```

```sql
SELECT * FROM pgr_dijkstra(
    'SELECT id, source, target, cost, reverse_cost FROM edge_table',
    2, 5
);
```

```
seq | path_seq | node | edge | cost | agg_cost
-----+----------+------+------+------+----------
 1 | 1 | 2 | 4 | 1 | 0
 2 | 2 | 5 | -1 | 0 | 1
(2 rows)
```

When you pass an array we get a combined result:

```sql
SELECT * FROM pgr_dijkstra(
    'SELECT id, source, target, cost, reverse_cost FROM edge_table',
    2, array[3,5]
);
```

```sql
78 Chapter 6. Routing functions
```

### 6.1.9 Driving Distance post-processing

- `pgr_alphaShape` - Alpha shape computation
- `pgr_pointsAsPolygon` - Polygon around set of points
pgr_drivingDistance (V2.0)

Name

pgr_drivingDistance - Returns the driving distance from a start node.

Synopsis

This function computes a Dijkstra shortest path solution then extracts the cost to get to each node in the network from the starting node. Using these nodes and costs it is possible to compute constant drive time polygons. Returns a set of `pgr_costResult` (seq, id1, id2, cost) rows, that make up a list of accessible points.

```
pgr_costResult[] pgr_drivingDistance(text sql, integer source, double precision distance, boolean directed, boolean has_rcost);
```

**Warning:** This signature is being deprecated on version 2.1. Please use it without the `has_rcost` flag instead:

```
pgr_drivingDistance(sql, start_v, distance, directed)
```

See `pgr_drivingDistance`

Description

**sql** a SQL query, which should return a set of rows with the following columns:

```
SELECT id, source, target, cost [,reverse_cost] FROM edge_table
```

- **id** int4 identifier of the edge
- **source** int4 identifier of the source vertex
- **target** int4 identifier of the target vertex
- **cost** float8 value, of the edge traversal cost. A negative cost will prevent the edge from being inserted in the graph.
- **reverse_cost** (optional) the cost for the reverse traversal of the edge. This is only used when the `directed` and `has_rcost` parameters are `true` (see the above remark about negative costs).
- **source** int4 id of the start point
- **distance** float8 value in edge cost units (not in projection units - they might be different).
- **directed** true if the graph is directed
- **has_rcost** if `true`, the `reverse_cost` column of the SQL generated set of rows will be used for the cost of the traversal of the edge in the opposite direction.

Returns set of `pgr_costResult[]`:

- **seq** row sequence
- **id1** node ID
- **id2** edge ID (this is probably not a useful item)
- **cost** cost to get to this node ID

**Warning:** You must reconnect to the database after `CREATE EXTENSION pgrouting`. Otherwise the function will return Error computing path: std::bad_alloc.

Chapter 6. Routing functions
History

- Renamed in version 2.0.0

Examples

- Without `reverse_cost`

```sql
SELECT seq, id1 AS node, cost
FROM pgr_drivingDistance(
    'SELECT id, source, target, cost FROM edge_table',
    7, 1.5, false, false
);
```

<table>
<thead>
<tr>
<th>seq</th>
<th>node</th>
<th>cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>7</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>8</td>
<td>1</td>
</tr>
</tbody>
</table>

(2 rows)

- With `reverse_cost`

```sql
SELECT seq, id1 AS node, cost
FROM pgr_drivingDistance(
    'SELECT id, source, target, cost, reverse_cost FROM edge_table',
    7, 1.5, true, true
);
```

<table>
<thead>
<tr>
<th>seq</th>
<th>node</th>
<th>cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>7</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>8</td>
<td>1</td>
</tr>
</tbody>
</table>

(5 rows)

The queries use the Sample Data network.

**pgr_drivingDistance**

**Name**

`pgr_drivingDistance` - Returns the driving distance from a start node.

Fig. 6.2: Boost Graph Inside
Synopsis

Using Dijkstra algorithm, extracts all the nodes that have costs less than or equal to the value \texttt{distance}. The edges extracted will conform the corresponding spanning tree.

The minimal signature:

\begin{verbatim}
pgr_drivingDistance(sql text, start_v bigint, distance float8) 
RETURNS SET OF (seq, node, edge, cost, agg_cost)
\end{verbatim}

Driving Distance from a single starting point:

\begin{verbatim}
pgr_drivingDistance(sql text, start_vid bigint, distance float8, directed boolean) 
RETURNS SET OF (seq, node, edge, cost, agg_cost)
\end{verbatim}

Driving Distance from a multiple starting points:

\begin{verbatim}
pgr_drivingDistance(sql text, start_vids anyarray, distance float8, 
directed boolean default true, 
equicost boolean default false) 
RETURNS SET OF (seq, start_vid, node, edge, cost, agg_cost)
\end{verbatim}

Description of the SQL query

\texttt{sql} a SQL query, which should return a set of rows with the following columns:

\begin{verbatim}
SELECT id, source, target, cost [,reverse_cost] FROM edge_table
\end{verbatim}

- \texttt{id} ANY-INTEGER identifier of the edge.
- \texttt{source} ANY-INTEGER identifier of the source vertex of the edge.
- \texttt{target} ANY-INTEGER identifier of the target vertex of the edge.
- \texttt{cost} ANY-NUMERICAL value of the edge traversal cost. A negative cost will prevent the edge (source, target) from being inserted in the graph.
- \texttt{reverse_cost} ANY-NUMERICAL (optional) the value for the reverse traversal of the edge. A negative cost will prevent the edge (target, source) from being inserted in the graph.

Where:

- \texttt{ANY-INTEGER} smallint, int, bigint
- \texttt{ANY-NUMERICAL} smallint, int, bigint, real, float

Description of the parameters of the signatures

- \texttt{sql} SQL query as described above.
- \texttt{start_v} BIGINT id of the starting vertex.
- \texttt{start_v} array[ANY-INTEGER] array of id of starting vertices.
- \texttt{distance} FLOAT Upper limit for the inclusion of the node in the result.
- \texttt{directed} boolean (optional). When false the graph is considered as Undirected. Default is true which considers the graph as Directed.
equicost boolean (optional). When true the node will only appear in the closest start_v list. Default is false which resembles several calls using the single starting point signatures. Tie brakes are arbitrarily.

Description of the return values

Returns set of (seq [, start_v], node, edge, cost, agg_cost)

- seq INT row sequence.
- start_v BIGINT id of the starting vertex. Used when multiple starting vertices are in the query.
- node BIGINT id of the node within the limits from start_v.
- edge BIGINT id of the edge used to arrive to node. 0 when the node is the start_v.
- cost FLOAT cost to traverse edge.
- agg_cost FLOAT total cost from start_v to node.

Examples for queries marked as directed with cost and reverse_cost columns

The examples in this section use the following Graph 1: Directed, with cost and reverse cost

```
SELECT * FROM pgr_drivingDistance(
  'SELECT id, source, target, cost, reverse_cost FROM edge_table',
  2, 3
);
```

```
ride | node | edge | cost | agg_cost
-----+------+------+------+----------
  1 |  1 |   1 |   1 |     1
  2 |  2 |  -1 |  0 |     0
  3 |  5 |   4 |   1 |     1
  4 |  6 |   8 |   1 |     2
  5 | 11 |  12 |   1 |     3
  6 | 10 |  10 |   1 |     2
  7 | 13 |  14 |   1 |     3
  8 |  9 |   9 |   1 |     3
  9 |  7 |   6 |   1 |     3
 10 |  8 |   7 |   1 |     2
```

(10 rows)

```
SELECT * FROM pgr_drivingDistance(
  'SELECT id, source, target, cost, reverse_cost FROM edge_table',
  13, 3
);
```

```
ride | node | edge | cost | agg_cost
-----+------+------+------+----------
  1 |  2 |   4 |   1 |     3
  2 |  5 |  10 |   1 |     2
  3 |  6 |   8 |   1 |     3
  4 | 11 |  12 |   1 |     2
  5 | 10 |  14 |   1 |     1
  6 | 12 |  13 |   1 |     3
  7 | 13 |  -1 |  0 |     0
  8 |  8 |   7 |   1 |     3
```

(8 rows)

```
SELECT * FROM pgr_drivingDistance(
  'SELECT id, source, target, cost, reverse_cost FROM edge_table',
  array[2,13], 3
);
```

```
ride | from_v | node | edge | cost | agg_cost
-----+--------+------+------+------+----------
  1 |      2 |   4 |   1 |     3
  2 |      5 |  10 |   1 |     2
  3 |      6 |   8 |   1 |     3
  4 |     11 |  12 |   1 |     2
  5 |     10 |  14 |   1 |     1
  6 |     12 |  13 |   1 |     3
  7 |     13 |  -1 |  0 |     0
  8 |      8 |   7 |   1 |     3
```

(10 rows)
Examples for queries marked as undirected with cost and reverse_cost columns

The examples in this section use the following Graph 2: Undirected, with cost and reverse cost

```
SELECT * FROM pgr_drivingDistance(
    'SELECT id, source, target, cost, reverse_cost FROM edge_table',
    2, 3, false
);
```

```
seq | from_v | node | edge | cost | agg_cost
------------------------------------------
1   | 1     | 1    | 1    | 1    | 1
2   | 2     | 2    | -1   | 0    | 0
3   | 3     | 2    | 1    | 1    | 1
4   | 4     | 3    | 1    | 2    | 2
5   | 5     | 4    | 1    | 1    | 2
6   | 6     | 8    | 1    | 1    | 3
7   | 7     | 11   | 12   | 1    | 3
8   | 8     | 10   | 10   | 1    | 2
9   | 9     | 13   | 14   | 1    | 3
10  | 10    | -1   | 0    | 0    | 0
11  | 13    | 12   | 13   | 1    | 3
12  | 13    | 8    | 7    | 1    | 3
```

(11 rows)
### 6.1. Routing Functions

```sql
SELECT * FROM pgr_drivingDistance(
    'SELECT id, source, target, cost, reverse_cost FROM edge_table',
    13, 3, false
);
```

pgr_alphaShape

Name

pgr_alphaShape — Core function for alpha shape computation.

Synopsis

Returns a table with (x, y) rows that describe the vertices of an alpha shape.
table() pgr_alphaShape(text sql [, float8 alpha]);

Description

sql  text a SQL query, which should return a set of rows with the following columns:

<table>
<thead>
<tr>
<th>id</th>
<th>int4   identifier of the vertex</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>float8 x-coordinate</td>
</tr>
<tr>
<td>y</td>
<td>float8 y-coordinate</td>
</tr>
</tbody>
</table>

alpha (optional) float8 alpha value. If specified alpha value equals 0 (default), then optimal alpha value is used. For more information, see CGAL - 2D Alpha Shapes³.

Returns a vertex record for each row:

x  x-coordinate
y  y-coordinate

If a result includes multiple outer/inner rings, return those with separator row (x=NULL and y=NULL).

History

• Renamed in version 2.0.0
• Added alpha argument with default 0 (use optimal value) in version 2.1.0
• Supported to return multiple outer/inner ring coordinates with separator row (x=NULL and y=NULL) in version 2.1.0

Examples

In the alpha shape code we have no way to control the order of the points so the actual output you might get could be similar but different. The simple query is followed by a more complex one that constructs a polygon and computes the areas of it. This should be the same as the result on your system. We leave the details of the complex query to the reader as an exercise if they wish to decompose it into understandable pieces or to just copy and paste it into a SQL window to run.

```
SELECT * FROM pgr_alphaShape('SELECT id, x, y FROM vertex_table');
```

```
+---+---+
<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>3</td>
</tr>
</tbody>
</table>
(6 rows)
```

```
SELECT round(ST_Area(ST_MakePolygon(ST_AddPoint(foo.openline, ST_StartPoint(foo.openline))))::numeric, 2) AS st_area
FROM (SELECT ST_MakeLine(points ORDER BY id) AS openline
    FROM (SELECT ST_MakePoint(x, y) AS points, row_number() over() AS id
          FROM pgr_alphaShape('SELECT id, x, y FROM vertex_table')
         ) AS a) AS foo;
```

³http://doc.cgal.org/latest/Alpha_shapes_2/group__PkgAlphaShape2.html
The queries use the Sample Data network.

### pgr_pointsAsPolygon

**Name**

pgr_pointsAsPolygon — Draws an alpha shape around given set of points.

**Synopsis**

Returns the alpha shape as (multi)polygon geometry.

```sql
geometry pgr_pointsAsPolygon(text sql [, float8 alpha]);
```

**Description**

- `sql` text a SQL query, which should return a set of rows with the following columns:
  ```sql
  SELECT id, x, y FROM vertex_result;
  ```
  - `id` int4 identifier of the vertex
x  float8 x-coordinate
y  float8 y-coordinate

alpha (optional) float8 alpha value. If specified alpha value equals 0 (default), then optimal alpha value is used. For more information, see CGAL - 2D Alpha Shapes\(^4\).

Returns a (multi)polygon geometry (with holes).

**History**

- Renamed in version 2.0.0
- Added alpha argument with default 0 (use optimal value) in version 2.1.0
- Supported to return a (multi)polygon geometry (with holes) in version 2.1.0

**Examples**

In the following query there is no way to control which point in the polygon is the first in the list, so you may get similar but different results than the following which are also correct. Each of the pgr_pointsAsPolygon queries below is followed by one the compute the area of the polygon. This area should remain constant regardless of the order of the points making up the polygon.

```
SELECT ST_AsText(pgr_pointsAsPolygon('SELECT id, x, y FROM vertex_table'));
```

```
----------------------------------------
POLYGON((2 4,4 3,4 2,4 1,2 0,0 2,2 4))
(1 row)
```

```
SELECT round(ST_Area(pgr_pointsAsPolygon('SELECT id, x, y FROM vertex_table'))::numeric, 2) AS st_area;
```

```
st_area
---------
 10.00
(1 row)
```

```
SELECT ST_AsText(pgr_pointsAsPolygon('SELECT id::integer, ST_X(the_geom)::float AS x, ST_Y(the_geom)::float AS y FROM edge_table_vertices_pgr'));
```

```
----------------------------------------------------------
POLYGON((2 4,3.5 4,4 3,4 2,4 1,2 0,0 2,0.5 3.5,2 4))
(1 row)
```

```
SELECT round(ST_Area(pgr_pointsAsPolygon('SELECT id::integer, ST_X(the_geom)::float AS x, ST_Y(the_geom)::float AS y FROM edge_table_vertices_pgr'))::numeric, 2) AS st_area;
```

```
st_area
---------
 11.75
```

The queries use the Sample Data network.

6.1. Routing Functions 99
6.1.10 pgr_kDijkstra - Multiple destination Shortest Path Dijkstra

Name

- pgr_kdijkstraCost - Returns the costs for K shortest paths using Dijkstra algorithm.
- pgr_kdijkstraPath - Returns the paths for K shortest paths using Dijkstra algorithm.

Synopsis

These functions allow you to have a single start node and multiple destination nodes and will compute the routes to all the destinations from the source node. Returns a set of pgr_costResult or pgr_costResult3. pgr_kdijkstraCost returns one record for each destination node and the cost is the total code of the route to that node. pgr_kdijkstraPath returns one record for every edge in that path from source to destination and the cost is to traverse that edge.

```
pgr_costResult[] pgr_kdijkstraCost(text sql, integer source, integer[] targets, boolean directed, boolean has_rcost);
pgr_costResult3[] pgr_kdijkstraPath(text sql, integer source, integer[] targets, boolean directed, boolean has_rcost);
```

Description

```
sql a SQL query, which should return a set of rows with the following columns:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>int4</td>
<td>identifier of the edge</td>
</tr>
<tr>
<td>source</td>
<td>int4</td>
<td>identifier of the source vertex</td>
</tr>
<tr>
<td>target</td>
<td>int4</td>
<td>identifier of the target vertex</td>
</tr>
<tr>
<td>cost</td>
<td>float8</td>
<td>value, of the edge traversal cost. A negative cost will prevent the edge from being inserted in the graph.</td>
</tr>
<tr>
<td>reverse_cost</td>
<td>float8</td>
<td>(optional) the cost for the reverse traversal of the edge. This is only used when the directed and has_rcost parameters are true (see the above remark about negative costs).</td>
</tr>
</tbody>
</table>
```

source  int4 id of the start point

targets  int4[] an array of ids of the end points

directed  true if the graph is directed

has_rcost  if true, the reverse_cost column of the SQL generated set of rows will be used for the cost of the traversal of the edge in the opposite direction.

pgr_kdijkstraCost returns set of pgr_costResult[]:

```
seq row sequence
id1 path vertex source id (this will always be source start point in the query).
id2 path vertex target id

cost cost to traverse the path from id1 to id2. Cost will be -1.0 if there is no path to that target vertex id.
```

pgr_kdijkstraPath returns set of pgr_costResult3[] - Multiple Path Results with Cost:

```
seq row sequence
id1 path target id (identifies the target path).
```
id2  path edge source node id
id3  path edge id (-1 for the last row)
       cost  cost to traverse this edge or -1.0 if there is no path to this target

History

• New in version 2.0.0

Examples

• Returning a cost result

```sql
SELECT seq, id1 AS source, id2 AS target, cost FROM pgr_kdijkstraCost(
  'SELECT id, source, target, cost FROM edge_table',
  10, array[4,12], false, false
);
```

```
seq | source | target | cost
-----+--------+--------+------
0 | 10 | 4 | 4
1 | 10 | 12 | 2
(2 rows)
```

```sql
SELECT seq, id1 AS path, id2 AS node, id3 AS edge, cost
FROM pgr_kdijkstraPath(
  'SELECT id, source, target, cost FROM edge_table',
  10, array[4,12], false, false
);
```

```
seq | path | node | edge | cost
-----+------+------+------+------
0 | 4 | 10 | 12 | 1
1 | 4 | 11 | 13 | 1
2 | 4 | 12 | 15 | 1
3 | 4 | 9 | 16 | 1
4 | 4 | 4 | -1 | 0
5 | 12 | 10 | 12 | 1
6 | 12 | 11 | 13 | 1
7 | 12 | 12 | -1 | 0
(8 rows)
```

• Returning a path result

```sql
SELECT id1 AS path, st_astext(st_linemerge(st_union(b.the_geom))) AS the_geom
FROM pgr_kdijkstraPath(
  'SELECT id, source, target, cost FROM edge_table',
  10, array[4,12], false, false
) a,
    edge_table b
WHERE a.id3=b.id
GROUP by id1
ORDER by id1;
```

```
path | the_geom
-----+---------------------------------
4 | LINESTRING(2 3,3 3,4 3,4 2,4 1)
12 | LINESTRING(2 3,3 3,4 3)
(2 rows)
```

There is no assurance that the result above will be ordered in the direction of flow of the route, ie: it might be reversed. You will need to check if st_startPoint() of the route is the same as the start node location and

6.1. Routing Functions
if it is not then call \texttt{st\_reverse()} to reverse the direction of the route. This behavior is a function of PostGIS functions \texttt{st\_linemerge()} and \texttt{st\_union()} and not \texttt{pgRouting}.

\subsection*{6.1.11 pgr\_ksp - Multiple shortest Paths based on Dijkstra}

\section*{Version 2.0 (deprecated)}

- \texttt{pgr\_ksp} - Multiple shortest Paths based on Dijkstra

\section*{Version 2.1}

- \texttt{pgr\_ksp} - Multiple shortest Paths based on Dijkstra

\subsection*{pgr\_ksp (V 2.0) - K-Shortest Path}

\textbf{Name} \quad \texttt{pgr\_ksp} — Returns the “K” shortest paths.

\textbf{Synopsis} \quad The K shortest path routing algorithm based on Yen’s algorithm. “K” is the number of shortest paths desired. Returns a set of \texttt{pgr\_costResult3} (seq, id1, id2, id3, cost) rows, that make up a path.

\begin{verbatim}
pgr\_costResult3[] pgr\_ksp(sql text, source integer, target integer, paths integer, has\_rcost boolean);
\end{verbatim}

\textbf{Warning:} This signature is being deprecated in version 2.1, Please use it without the \texttt{has\_rcost} flag instead.

- for undirected graph. \texttt{pgr\_ksp(sql, source, target, distance, directed:=false)}
- for directed graph. \texttt{pgr\_ksp(sql, source, target, distance, directed:=true)}

\textbf{See} \texttt{pgr\_ksp - K-Shortest Path}

\textbf{Description} \quad \texttt{sql} a SQL query, which should return a set of rows with the following columns:

\begin{verbatim}
SELECT id, source, target, cost, [,reverse\_cost] FROM edge_table
\end{verbatim}

- \texttt{id int4} identifier of the edge
- \texttt{source int4} identifier of the source vertex
- \texttt{target int4} identifier of the target vertex
- \texttt{cost float8} value, of the edge traversal cost. A negative cost will prevent the edge from being inserted in the graph.
- \texttt{reverse\_cost} (optional) the cost for the reverse traversal of the edge. This is only used when \texttt{has\_rcost} the parameter is \texttt{true} (see the above remark about negative costs).
- \texttt{source int4} id of the start point
- \texttt{target int4} id of the end point
paths  int4 number of alternative routes

has_rcost  if true, the reverse_cost column of the SQL generated set of rows will be used for
the cost of the traversal of the edge in the opposite direction.

Returns set of pgr_costResult[]:

seq  sequence for ordering the results
id1  route ID
id2  node ID
id3  edge ID (0 for the last row)
cost  cost to traverse from id2 using id3

History

• New in version 2.0.0

Examples

• Without reverse_cost

```
SELECT seq, id1 AS route, id2 AS node, id3 AS edge, cost
FROM pgr_ksp('SELECT id, source, target, cost FROM edge_table',
7, 12, 2, false)
;
seq | route | node | edge | cost
--------------------------------------
 0 | 0 | 7 | 6 | 1
 1 | 0 | 8 | 7 | 1
 2 | 0 | 5 | 8 | 1
 3 | 0 | 6 | 9 | 1
 4 | 0 | 9 | 15 | 1
 5 | 0 | 12 | -1 | 0
 6 | 1 | 7 | 6 | 1
 7 | 1 | 8 | 7 | 1
 8 | 1 | 5 | 8 | 1
 9 | 1 | 6 | 11 | 1
10 | 1 | 11 | 13 | 1
11 | 1 | 12 | -1 | 0
```

(12 rows)

• With reverse_cost

```
SELECT seq, id1 AS route, id2 AS node, id3 AS edge, cost
FROM pgr_ksp('SELECT id, source, target, cost, reverse_cost FROM edge_table',
7, 12, 2, true)
;
seq | route | node | edge | cost
--------------------------------------
 0 | 0 | 7 | 6 | 1
 1 | 0 | 8 | 7 | 1
 2 | 0 | 5 | 8 | 1
 3 | 0 | 6 | 9 | 1
 4 | 0 | 9 | 15 | 1
 5 | 0 | 12 | -1 | 0
 6 | 1 | 7 | 6 | 1
 7 | 1 | 8 | 7 | 1
```

6.1. Routing Functions
The queries use the *Sample Data* network.

**See Also**
- `pgr_costResult3[]` - Multiple Path Results with Cost

**pgr_ksp** - K-Shortest Path

**Name**  
pgr_ksp — Returns the “K” shortest paths.

**Synopsis**  
The K shortest path routing algorithm based on Yen’s algorithm. “K” is the number of shortest paths desired.

**The minimal signature:**

```sql
pgr_ksp(TEXT sql_q, BIGINT start_vid, BIGINT end_vid, INTEGER k);
```

**Returns set of:**

- `(seq, path_id, path_seq, node, edge, cost, agg_cost)` or **EMPTY SET**

**The full signature:**

```sql
pgr_ksp(TEXT edges_sql, BIGINT start_vid, BIGINT end_vid, INTEGER k,
       BOOLEAN directed:=true, BOOLEAN heap_paths:=false);
```

**Returns set of:**

- `(seq, path_id, path_seq, node, edge, cost, agg_cost)` or **EMPTY SET**

**Description of the SQL query**  
General description of the `edges_sql`

```sql
SELECT id, source, target, cost [,reverse_cost] FROM ...
```

- `sql_q` a SQL query, which returns a set of rows with the following columns:
  - `id` ANY-INTEGER identifier of the edge.
  - `source` ANY-INTEGER identifier of the source vertex of the edge.
  - `target` ANY-INTEGER identifier of the target vertex of the edge.
  - `cost` ANY-NUMERICAL value of the edge traversal cost. A negative cost will prevent the edge `(source,target)` from being inserted in the graph.
reverse_cost  ANY-NUMERICAL (optional) the value for the reverse traversal of the edge. A negative cost will prevent the edge (target, source) from being inserted in the graph.

Where:

ANY-INTEGER  smallint, int, bigint

ANY-NUMERICAL  smallint, int, bigint, real, float

Description of the parameters of the signatures

sql_q  TEXT  SQL query as described above.

start_vid  BIGINT  id of the starting vertex.

direct  INTEGER  The desired number of paths.

e_drected BOOLEAN (optional). When false the graph is considered as Undirected. Default is true which considers the graph as Directed.

heap_paths  BOOLEAN (optional). When true returns all the paths stored in the process heap. Default is false which only returns k paths.

Roughly, if the shortest path has N edges, the heap will contain about than N * k paths for small value of k and k > 1.

Description of the return values  Returns set of (seq, path_seq, path_id, node, edge, cost, agg_cost)

seq  INT  sequential number starting from 1.

path_seq  INT  relative position in the path of node and edge. Has value 1 for the beginning of a path.

path_id  BIGINT  path identifier. The ordering of the paths. For two paths i, j if i < j then agg_cost(i) <= agg_cost(j).

node  BIGINT  id of the node in the path.

e_dge  BIGINT  id of the edge used to go from node to the next node in the path sequence. -1 for the last node of the route.

cost  FLOAT  cost to traverse from node using edge to the next node in the path sequence.

agg_cost  FLOAT  total cost from start_vid to node.

Warning:  During the transition to 3.0, because pgr_ksp version 2.0 doesn’t have defined a directed flag nor a heap_path flag, when pgr_ksp is used with only one flag version 2.0 will be used.

Examples to handle the one flag to choose signatures  The examples in this section use the following Graph 1: Directed, with cost and reverse cost

```
SELECT * FROM pgr_ksp(
    'SELECT id, source, target, cost, reverse_cost FROM edge_table',
    2, 12, 2,
    true -- takes the (V2.0) signature (has_rcost = true and works on directed graph)
);
```

```
SELECT * FROM pgr_ksp(
    'SELECT id, source, target, cost, reverse_cost FROM edge_table',
    2, 12, 2, heap_paths:=true
);```
Examples for queries marked as undirected with cost and reverse_cost columns

The examples in this section use the following Graph 2: Undirected, with cost and reverse cost

```sql
SELECT * FROM pgr_ksp(
    'SELECT id, source, target, cost, reverse_cost FROM edge_table',
    2, 12, 2, directed:=false
);
seq | path_id | path_seq | node | edge | cost | agg_cost
--------------------------
    1 |       1 |        1 |     2 |     2 |    1 |       0
    2 |       2 |        1 |     3 |     4 |    1 |       1
    3 |       1 |        2 |     4 |     16|    1 |       3
    4 |       1 |        3 |     5 |     12|   -1 |       0
    5 |       2 |        1 |     6 |     9 |    1 |       1
    6 |       2 |        2 |     7 |     15|    1 |       2
    7 |       2 |        3 |     8 |     11|    1 |       4
    8 |       2 |        4 |     9 |     13|    1 |       3
    9 |       2 |        5 |    10 |     13|    1 |       3
   10 |       3 |        1 |     2 |     4 |    1 |       0
   11 |       3 |        2 |     3 |     9 |    1 |       1

### 6.1.12 pgr_tsp - Traveling Sales Person

#### Name

- **pgr_tsp** - Returns the best route from a start node via a list of nodes.
- **pgr_tsp** - Returns the best route order when passed a distance matrix.
- **pgr_makeDistanceMatrix** - Returns a Euclidean distance matrix from the points provided in the SQL result.

#### Synopsis

The travelling salesman problem (TSP) or travelling salesperson problem asks the following question: Given a list of cities and the distances between each pair of cities, what is the shortest possible route that visits each city exactly once and returns to the origin city? This algorithm uses simulated annealing to return a high quality approximate solution. Returns a set of **pgr_costResult** (seq, id1, id2, cost) rows, that make up a path.

```sql
record[] pgr_tsp(matrix float[][] start integer);
record[] pgr_tsp(matrix float[][] start integer, end integer);
```

Returns a set of (seq, id1, id2, cost) that is the best order to visit the nodes in the matrix. `id1` is the index into the distance matrix. `id2` is the point id from the SQL.

If no `end_id` is supplied or it is -1 or equal to the `start_id` then the TSP result is assumed to be a circular loop returning back to the start. If `end_id` is supplied then the route is assumed to start and end the the designated ids.

```sql
record[] pgr_tsp(matrix float[][], start integer)
record[] pgr_tsp(matrix float[][], start integer, end integer)
```
Description

With Euclidean distances

The TSP solver is based on ordering the points using straight line (euclidean) distance between nodes. The implementation is using an approximation algorithm that is very fast. It is not an exact solution, but it is guaranteed that a solution is returned after certain number of iterations.

A SQL query, which should return a set of rows with the following columns:

```
SELECT id, x, y FROM vertex_table
```

- **id**: int4 identifier of the vertex
- **x**: float8 x-coordinate
- **y**: float8 y-coordinate
- **start_id**: int4 id of the start point
- **end_id**: int4 id of the end point. This is OPTIONAL, if include the route is optimized from start to end, otherwise it is assumed that the start and the end are the same point.

The function returns set of `pgr_costResult[]`:

- **seq**: row sequence
- **id1**: internal index to the distance matric
- **id2**: id of the node
- **cost**: cost to traverse from the current node to the next node.

Create a distance matrix

For users that need a distance matrix we have a simple function that takes SQL in SQL as described above and returns a record with `dmatrix` and `ids`.

```
SELECT dmatrix, ids FROM pgr_makeDistanceMatrix('SELECT id, x, y FROM vertex_table');
```

The function returns a record of `dmatrix`, `ids`:

- **dmatrix**: float8[][] a symetric Euclidean distance matrix based on SQL.
- **ids**: integer[] an array of ids as they are ordered in the distance matrix.

With distance matrix

For users, that do not want to use Euclidean distances, we also provide the ability to pass a distance matrix that we will solve and return an ordered list of nodes for the best order to visit each. It is up to the user to fully populate the distance matrix.

- **matrix**: float[][] distance matrix of points
- **start**: int4 index of the start point
- **end**: int4 (optional) index of the end node

1 There was some thought given to pre-calculating the driving distances between the nodes using Dijkstra, but then I read a paper (unfortunately I don’t remember who wrote it), where it was proved that the quality of TSP with euclidean distance is only slightly worse than one with real distance in case of normal city layout. In case of very sparse network or rivers and bridges it becomes more inaccurate, but still wholly satisfactory. Of course it is nice to have exact solution, but this is a compromise between quality and speed (and development time also). If you need a more accurate solution, you can generate a distance matrix and use that form of the function to get your results.
The end node is an optional parameter, you can just leave it out if you want a loop where the start is the depot and the route returns back to the depot. If you include the end parameter, we optimize the path from start to end and minimize the distance of the route while include the remaining points.

The distance matrix is a multidimensional PostgreSQL array type that must be \( N \times N \) in size.

The result will be \( N \) records of \([ \text{seq}, \text{id} ]\):

- \textit{seq} row sequence
- \textit{id} index into the matrix

**History**

- Renamed in version 2.0.0
- GAUL dependency removed in version 2.0.0

**Examples**

- Using SQL parameter (all points from the table, starting from 6 and ending at 5). We have listed two queries in this example, the first might vary from system to system because there are multiple equivalent answers. The second query should be stable in that the length optimal route should be the same regardless of order.

```sql
SELECT seq, id1, id2, round(cost::numeric, 2) AS cost
FROM pgr_tsp('SELECT id, x, y FROM vertex_table ORDER BY id', 6, 5);
```

```
seq | id1 | id2 | cost
-----+-----+-----+------
0 | 5 | 6 | 1.00
1 | 6 | 7 | 1.00
2 | 7 | 8 | 1.41
3 | 1 | 2 | 1.00
4 | 0 | 1 | 1.41
5 | 2 | 3 | 1.00
6 | 3 | 4 | 1.00
7 | 8 | 9 | 1.00
8 | 11 | 12 | 1.00
9 | 10 | 11 | 1.41
10 | 12 | 13 | 1.00
11 | 9 | 10 | 2.24
12 | 4 | 5 | 1.00
```

```
SELECT round(sum(cost)::numeric, 4) as cost
FROM pgr_tsp('SELECT id, x, y FROM vertex_table ORDER BY id', 6, 5);
```

```
cost
---------
15.4787
```

- Using distance matrix (A loop starting from 1)

When using just the start node you are getting a loop that starts with 1, in this case, and travels through the other nodes and is implied to return to the start node from the last one in the list. Since this is a circle there are at least two possible paths, one clockwise and one counter-clockwise that will have the same length and be equall valid. So in the following example it is also possible to get back a sequence of ids = \{1,0,3,2\} instead of the \{1,2,3,0\} sequence listed below.

\[\text{http://www.postgresql.org/docs/9.1/static/arrays.html}\]
SELECT seq, id FROM pgr_tsp('{{0,1,2,3},{1,0,4,5},{2,4,0,6},{3,5,6,0}}'::float8[],1);

<table>
<thead>
<tr>
<th>seq</th>
<th>id</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
</tr>
</tbody>
</table>
(4 rows)

- Using distance matrix (Starting from 1, ending at 2)

SELECT seq, id FROM pgr_tsp('{{0,1,2,3},{1,0,4,5},{2,4,0,6},{3,5,6,0}}'::float8[],1,2);

<table>
<thead>
<tr>
<th>seq</th>
<th>id</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
</tr>
</tbody>
</table>
(4 rows)

- Using the vertices table edge_table_vertices_pgr generated by `pgr_createTopology`. Again we have two queries where the first might vary and the second is based on the overall path length.

SELECT seq, id1, id2, round(cost::numeric, 2) AS cost FROM pgr_tsp('SELECT id::integer, st_x(the_geom) as x,st_y(the_geom) as y FROM edge_table_vertices_pgr ORDER BY id', 6, 5);

<table>
<thead>
<tr>
<th>seq</th>
<th>id1</th>
<th>id2</th>
<th>cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>5</td>
<td>6</td>
<td>0.00</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>11</td>
<td>0.00</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>3</td>
<td>1.41</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>4</td>
<td>0.00</td>
</tr>
<tr>
<td>4</td>
<td>11</td>
<td>12</td>
<td>0.00</td>
</tr>
<tr>

The queries use the Sample Data network.

See Also

- `pgr_costResult[]`
6.1.13 pgr_trsp - Turn Restriction Shortest Path (TRSP)

Name

pgr_trsp — Returns the shortest path with support for turn restrictions.

Synopsis

The turn restricted shortest path (TRSP) is a shortest path algorithm that can optionally take into account complicated turn restrictions like those found in real work navigable road networks. Performance wise it is nearly as fast as the A* search but has many additional features like it works with edges rather than the nodes of the network. Returns a set of pgr_costResult (seq, id1, id2, cost) rows, that make up a path.

```
pgr_costResult[] pgr_trsp(sql text, source integer, target integer,
    directed boolean, has_rcost boolean [,restrict_sql text]);

pgr_costResult[] pgr_trsp(sql text, source_edge integer, source_pos float8,
    target_edge integer, target_pos float8,
    directed boolean, has_rcost boolean [,restrict_sql text]);

pgr_costResult3[] pgr_trspViaVertices(sql text, vids integer[],
    directed boolean, has_reverse_cost boolean
    [, turn_restrict_sql text]);

pgr_costResult3[] pgr_trspViaEdges(sql text, eids integer[], pcts float8[],
    directed boolean, has_reverse_cost boolean
    [, turn_restrict_sql text]);
```

Description

The Turn Restricted Shortest Path algorithm (TRSP) is similar to the Shooting Star algorithm in that you can specify turn restrictions.

The TRSP setup is mostly the same as Dijkstra shortest path with the addition of an optional turn restriction table. This provides an easy way of adding turn restrictions to a road network by placing them in a separate table.

SQL a SQL query, which should return a set of rows with the following columns:

```
SELECT id, source, target, cost, [reverse_cost] FROM edge_table
```

- id int4 identifier of the edge
- source int4 identifier of the source vertex
- target int4 identifier of the target vertex
- cost float8 value, of the edge traversal cost. A negative cost will prevent the edge from being inserted in the graph.
- reverse_cost (optional) the cost for the reverse traversal of the edge. This is only used when the directed and has_rcost parameters are true (see the above remark about negative costs).
- source int4 NODE id of the start point
- target int4 NODE id of the end point
- directed true if the graph is directed
has_rcost if true, the reverse_cost column of the SQL generated set of rows will be used for the cost of the traversal of the edge in the opposite direction.

restrict_sql (optional) a SQL query, which should return a set of rows with the following columns:

```sql
SELECT to_cost, target_id, via_path FROM restrictions
```

to_cost float8 turn restriction cost
target_id int4 target id
via_path text commar seperated list of edges in the reverse order of rule

Another variant of TRSP allows to specify EDGE id of source and target together with a fraction to interpolate the position:

```plaintext
source_edge int4 EDGE id of the start edge
source_pos float8 fraction of 1 defines the position on the start edge
target_edge int4 EDGE id of the end edge
target_pos float8 fraction of 1 defines the position on the end edge
```

Returns set of `pgr_costResult[]`:

- seq row sequence
- id1 node ID
- id2 edge ID (-1 for the last row)
- cost cost to traverse from id1 using id2

History

- New in version 2.0.0

Support for Vias

---

**Warning:** The Support for Vias functions are prototypes. Not all corner cases are being considered.

We also have support for vias where you can say generate a from A to B to C, etc. We support both methods above only you pass an array of vertices or and array of edges and percentage position along the edge in two arrays.

sql a SQL query, which should return a set of rows with the following columns:

```sql
SELECT id, source, target, cost, [,reverse_cost] FROM edge_table
```

- id int4 identifier of the edge
- source int4 identifier of the source vertex
- target int4 identifier of the target vertex
- cost float8 value, of the edge traversal cost. A negative cost will prevent the edge from being inserted in the graph.
- reverse_cost (optional) the cost for the reverse traversal of the edge. This is only used when the directed and has_rcost parameters are true (see the above remark about negative costs).
- vids int4[] An ordered array of NODE id the path will go through from start to end.
- directed true if the graph is directed
has_cost if true, the reverse_cost column of the SQL generated set of rows will be used for the cost of the traversal of the edge in the opposite direction.

restrict_sql (optional) a SQL query, which should return a set of rows with the following columns:

```
SELECT to_cost, target_id, via_path FROM restrictions
```

to_cost float8 turn restriction cost
target_id int4 target id
via_path text comma separated list of edges in the reverse order of rule

Another variant of TRSP allows to specify EDGE id together with a fraction to interpolate the position:

eids int4 An ordered array of EDGE id that the path has to traverse
pcts float8 An array of fractional positions along the respective edges in eids, where 0.0 is the start of the edge and 1.0 is the end of the edge.

Returns set of pgr_costResult[]:

seq row sequence
id1 route ID
id2 node ID
id3 edge ID (-1 for the last row)
cost cost to traverse from id2 using id3

History

• Via Support prototypes new in version 2.1.0

Examples

• Without turn restrictions

```
SELECT seq, id1 AS node, id2 AS edge, cost
FROM pgr_trsp(
    'SELECT id, source, target, cost FROM edge_table',
    7, 12,
    false, false
);
```

<table>
<thead>
<tr>
<th>seq</th>
<th>node</th>
<th>edge</th>
<th>cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>7</td>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>8</td>
<td>7</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>5</td>
<td>8</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>6</td>
<td>11</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>11</td>
<td>13</td>
<td>1</td>
</tr>
<tr>
<td>5</td>
<td>12</td>
<td>-1</td>
<td>0</td>
</tr>
</tbody>
</table>

(6 rows)

• With turn restrictions

Turn restrictions require additional information, which can be stored in a separate table:

```
CREATE TABLE restrictions {
    rid serial,
    to_cost double precision,
    to_edge integer,
    from_edge integer,
    via text
}
```
Then a query with turn restrictions is created as:

```sql
SELECT seq, id1 AS node, id2 AS edge, cost
FROM pgr_trsp(
    'SELECT id, source, target, cost FROM edge_table',
    7, 12,
    false, false,
    'SELECT to_cost, to_edge AS target_id,
    from_edge || coalesce('', '' || via, '') AS via_path
    FROM restrictions'
);
```

An example query using vertex ids and via points:

```sql
SELECT * FROM pgr_trspViaVertices(
    'SELECT id, source::INTEGER, target::INTEGER, cost,
    reverse_cost FROM edge_table',
    ARRAY[1,8,13,5]::INTEGER[],
    true, true,
    'SELECT to_cost, to_edge AS target_id, FROM_edge ||
    coalesce('', '' || via, '') AS via_path FROM restrictions');
```

An example query using edge ids and vias:

```sql
SELECT * FROM pgr_trspViaEdges(
    'SELECT id, source::INTEGER, target::INTEGER, cost,
    reverse_cost FROM edge_table',
    ARRAY[1,11,6]::INTEGER[],
    6.1. Routing Functions 117
);
The queries use the Sample Data network.

Experimental and Proposed functions

This section contains new experimental or proposed signatures for any of the following sections:
- topology functions
- routing functions
- vehicle routing functions
- pre / post processing helper functions

We are including them so that the pgRouting community can evaluate them before including them as an official function of pgRouting.

Some of them are unsupported like the GSoC functions.
Experimental functions: Proposed by Steve Woodbridge

Convenience Functions

- *pgr_pointToEdgeNode* - convert a point geometry to a vertex_id based on closest edge.
- *pgr_flipEdges* - flip the edges in an array of geometries so the connect end to end.
- *pgr_textToPoints* - convert a string of \( x, y; x, y; \ldots \) locations into point geometries.
- *pgr_pointsToVids* - convert an array of point geometries into vertex ids.
- *pgr_pointsToDMatrix* - Create a distance matrix from an array of points.
- *pgr_vidsToDMatrix* - Create a distance matrix from an array of vertex_id.

9.1 Convenience Functions

The following functions are general purpose convenience functions that might be useful when building a larger application or handling input from say an Ajax handler.

- *pgr_pointToEdgeNode* - convert a point geometry to a vertex_id based on closest edge.
- *pgr_flipEdges* - flip the edges in an array of geometries so the connect end to end.
- *pgr_textToPoints* - convert a string of \( x, y; x, y; \ldots \) locations into point geometries.
- *pgr_pointsToVids* - convert an array of point geometries into vertex ids.

9.2 Distance Matrix Functions

These function my be helpful when you need to create or manipulate distance matricies, like for TSP or VRP related problems.

- *pgr_pointsToDMatrix* - Create a distance matrix from an array of points.
- *pgr_vidsToDMatrix* - Create a distance matrix from an array of vertex_id.
- *pgr_vidsToDMatrix* - Create a distance matrix from an array of vertex_id.

9.2.1 pgr_pointToEdgeNode

Name

*pgr_pointToEdgeNode* - Converts a point to a vertex_id based on closest edge.
Synopsis

The function returns:

- integer that is the vertex id of the closest edge in the edges table within the tol tolerance of pnt. The vertex is selected by projection the pnt onto the edge and selecting which vertex is closer along the edge.

```plaintext
integer pgr_pointToEdgeNode(edges text, pnt geometry, tol float8)
```

Description

Given an table edges with a spatial index on the_geom and a point geometry search for the closest edge within tol distance to the edges then compute the projection of the point onto the line segment and select source or target based on whether the projected point is closer to the respective end and return the source or target value.

Parameters

The function accepts the following parameters:

- `edges` text: The name of the edge table or view. (may contain the schema name AS well).
- `pnt` geometry: A point geometry object in the same SRID as edges.
- `tol` float8: The maximum search distance for an edge.

**Warning:** If no edge is within tol distance then return -1

The edges table must have the following columns:

- source
- target
- the_geom

History

- New in version 2.1.0

Examples

```sql
select pgr_pointToEdgeNode('edge_table', 'POINT(2 0)'::geometry, 0.02);
pgr_pointToEdgeNode
-------------------
    1
(1 row)
```

The example uses the Sample Data network.

See Also

- `pgr_pointsToVids` - convert an array of point geometries into vertex ids.
9.2.2 pgr_flipEdges

Name
pgr_flipEdges -

Synopsis
The function returns:

• geometry[]. An array of the input geometries with the geometries flipped end to end such that the geometries are oriented as a path from start to end.

geometry[] pgr_flipEdges(ga geometry[])

Description
Given an array of linestrings that are supposedly connected end to end like the results of a route, check the edges and flip any end for end if they do not connect with the previous segment and return the array with the segments flipped as appropriate.

Parameters

ga geometry[] An array of geometries, like the results of a routing query.

Warning:
• No checking is done for edges that do not connect.
• Input geometries MUST be LINESTRING or MULTILINESTRING.
• Only the first LINESTRING of a MULTILINESTRING is considered.

History
• New in version 2.1.0

Examples

```sql
select st_astext(e) from (select unnest (pgr_flipedges(ARRAY[
 'LINESTRING(2 1,2 2)':'geometry,
 'LINESTRING(2 2,2 3)':'geometry,
 'LINESTRING(2 2,2 3)':'geometry,
 'LINESTRING(2 2,3 2)':'geometry,
 'LINESTRING(2 3,4 2)':'geometry,
 'LINESTRING(4 1,4 2)':'geometry,
 'LINESTRING(3 1,4 1)':'geometry,
 'LINESTRING(2 1,3 1)':'geometry,
 'LINESTRING(2 0,2 1)':'geometry,
 'LINESTRING(2 0,2 1)':'geometry::geometry[]::geometry[]]) as e) as foo;
```

<table>
<thead>
<tr>
<th>st_astext</th>
</tr>
</thead>
<tbody>
<tr>
<td>LINESTRING(2 1,2 2)</td>
</tr>
<tr>
<td>LINESTRING(2 2,2 3)</td>
</tr>
<tr>
<td>LINESTRING(2 3,2 2)</td>
</tr>
<tr>
<td>LINESTRING(2 2,3 2)</td>
</tr>
<tr>
<td>LINESTRING(3 2,4 2)</td>
</tr>
<tr>
<td>LINESTRING(4 2,4 1)</td>
</tr>
</tbody>
</table>

See Also

9.2.3 pgr_textToPoints

Name

pgr_textToPoints - Converts a text string of the format “x,y;x,y;x,y;...” into an array of point geometries.

Synopsis

Given a text string of the format “x,y;x,y;x,y;...” and the srid to use, split the string and create an array of point geometries.

The function returns:

•

integer pgr_textToPoints(pnts text, srid integer DEFAULT (4326))

Description

Parameters

• pnts text A text string of the format “x,y;x,y;x,y;...” where x is longitude and y is latitude if used in lat-lon.
• srid integer The SRID to use when constructing the point geometry. If the parameter is absent it defaults to SRID:4326.

History

• New in version 2.1.0

Examples

```sql
select st_astext(g) from ( 
    select unnest( 
        pgr_textToPoints('0,0;1,1;1,0;0,1;1,4;1,5;0,4;0,5', 0) 
    ) as g 
) as foo; 
```

```
st_astext
------------
POINT(0 0)
POINT(1 1)
POINT(1 0)
POINT(0 1)
POINT(1 4)
POINT(1 5)
POINT(0 4)
```
See Also

• *pgr_pointToEdgeNode* - convert a point geometry to a node_id based on closest edge.
• *pgr_pointsToVids* - convert an array of point geometries into vertex ids.

9.2.4 pgr_pointsToVids

**Name**

pgr_pointsToVids - Converts an array of point geometries into vertex ids.

**Synopsis**

Given an array of point geometries and an edge table and a max search tol distance the function converts points into vertex ids using pgr_pointtoedgenode().

The function returns:

• integer[] - An array of vertex_id.

```sql
integer[] pgr_pointsToVids(pnts geometry[], edges text, tol float8 DEFAULT(0.01))
```

**Description**

**Parameters**

- **pnts**: geometry[] - An array of point geometries.
- **edges**: text - The edge table to be used for the conversion.
- **tol**: float8 - The maximum search distance for locating the closest edge.

**Warning:** You need to check the results for any vids=-1 which indicates if failed to locate an edge.

**History**

• New in version 2.1.0

**Examples**

```sql
select * from pgr_pointstovids(
    pgr_texttopoints('2,0;2,1;3,1;2,2;4,1;4,2;2,3;3,2', 0),
    'edge_table'
    -- tol is not specified, so we use the default of 0.01
);
```

pgr_pointsToVids
-------------------
{1,2,3,5,4,9,10,6}
(1 row)

This example uses the Sample Data network.
See Also

- pgr_pointToEdgeNode - convert a point geometry to the closest vertex_id of an edge.

9.2.5 pgr_pointsToDMatrix

Name

pgr_pointsToDMatrix - Creates a distance matrix from an array of points.

Synopsis

Create a distance symetric distance matrix suitable for TSP using Euclidean distances based on the st_distance(). You might want to create a variant of this the uses st_distance_sphere() or st_distance_spheriod() or some other function.

The function returns:

- record - with two fields as describe here
  - dmatrix float8[] - the distance matrix suitable to pass to pgrTSP() function.
  - ids integer[] - an array of ids for the distance matrix.

\[
\text{record pgr_pointsToDMatrix(pnts geometry[], OUT dmatrix double precision[], OUT ids integer[])}
\]

Description

Parameters

- pnts geometry[] - An array of point geometries.

Warning: The generated matrix will be symmetric as required for pgr_TSP.

History

- New in version 2.1.0

Examples

```sql
select unnest(dmatrix) from pgr_pointsToDMatrix(
  pgr_texttopoints('2,0;2,1;3,1;2,2;4,1;4,2;2,3;3,2', 0)
) limit 8;
```

```sql
unnest
--------------------
   0
   1
1.4142135623731
   2
2.23606797749979
2.82842712474619
   3
2.23606797749979
(8 rows)
```

```sql
select ids from pgr_pointstodmatrix(
)
```
pgr_texttopoints('2,0;2,1;3,1;2,2;4,1;4,2;2,3;3,2', 0)
);
ids
-------------------
{1,2,3,4,5,6,7,8}
(1 row)

See Also

- **pgr_vidsToDMatrix** - convert a point geometry to the closest vertex_id of an edge..
- **pgr_tsp** - Traveling Sales Person

### 9.2.6 pgr_vidsToDMatrix

#### Name

**pgr_vidsToDMatrix** - Creates a distances matrix from an array of vertex_id.

#### Synopsis

This function takes an array of vertex_id, the original array of points used to generate the array of vertex_id, an edge table name and a tol. It then computes kdijkstra() distances for each vertex to all the other vertices and creates a symmetric distance matrix suitable for TSP. The pnt array and the tol are used to establish a BBOX for limiting selection of edges. The extents of the points is expanded by tol.

The function returns:

- **record** - with two fields as describe here
  - `dmatrix` *float8[]* - the distance matrix suitable to pass to pgrTSP() function.
  - `ids` *integer[]* - an array of ids for the distance matrix.

```sql
record pgr_vidsToDMatrix(IN vids integer[], IN pnts geometry[], IN edges text, tol float8 DEFAULT (0.1))
```

#### Description

#### Parameters

- **vids** *integer[]* - An array of vertex_id.
- **pnts** *geometry[]* - An array of point geometries that approximates the extents of the vertex_id.
- **edges** *text* - The edge table to be used for the conversion.
- **tol** *float8* - The amount to expand the BBOX extents of pnts when building the graph.

#### Warning:

- we compute a symmetric matrix because TSP requires that so the distances are better the Euclidean but are not perfect
- kdijkstra() can fail to find a path between some of the vertex ids. We to not detect this other than the cost might get set to -1.0, so the dmatrix should be checked for this as it makes it invalid for TSP
History

• New in version 2.1.0

Examples

This example shows how this can be used in the context of feeding the results into pgr_tsp() function. We convert a text string of \texttt{x,y;x,y;...} into an array of points, then convert that into an array \texttt{vertex_id}, then create a distance matrix that gets feed into \texttt{pgr_tsp()} that returns the final result.

```sql
select * from pgr_tsp(
    select dmatrix::float8[]
    from pgr_vidstodmatrix(
        pgr_pointstovids(
            pgr_texttopoints('2,0;2,1;3,1;2,2;4,1;4,2;2,3;3,2', 0),
            'edge_table'),
            pgr_texttopoints('2,0;2,1;3,1;2,2;4,1;4,2;2,3;3,2', 0),
            'edge_table')
    )
);
```

seq | id
-----+----
0 | 1
1 | 3
2 | 7
3 | 5
4 | 4
5 | 2
6 | 6
7 | 0
(8 rows)

This example uses the \textit{Sample Data} network.

See Also

• \textit{pgr_textToPoints} - Create an array of points from a text string.

• \textit{pgr_tsp} - Traveling Sales Person

9.2.7 \textit{pgr_vidsToDMatrix}

Name

\textit{pgr_vidsToDMatrix} - Creates a distances matrix from an array of \texttt{vertex_id}.

Synopsis

This function takes an array of \texttt{vertex_id}, a sql statement to select the edges, and some boolean arguments to control the behavior. It then computes \texttt{kdijkstra()} distances for each vertex to all the other vertices and creates a distance matrix suitable for TSP.

The function returns:

• \texttt{dmatrix float8[]} - the distance matrix suitable to pass to \texttt{pgr_TSP()} function.

```sql
pgr_vidsToDMatrix(IN sql text, IN vids integer[], IN directed boolean, IN has_reverse_cost boolean)
```
Description

Parameters

- **sql** text - A SQL statement to select the edges needed for the solution.
- **vids** integer[] - An array of `vertex_id`.
- **directed** boolean - A flag to indicate if the graph is directed.
- **has_reverse_cost** boolean - A flag to indicate if the SQL has a column `reverse_cost`.
- **want_symmetric** boolean - A flag to indicate if you want a symmetric or asymmetric matrix. You will need a symmetric matrix for `pgr_TSP()`. If the matrix is asymmetric, the then the cell(i,j) and cell(j,i) will be set to the average of those two cells except if one or the other are -1.0 then it will take the value of the other cell. If both are negative they will be left alone.

**Warning:**
- `kdijkstra()` can fail to find a path between some of the vertex ids. We do not detect this other than the cost might get set to -1.0, so the `dmatrix` should be checked for this as it makes it invalid for TSP

History

- New in version 2.1.0

Examples

This example shows how this can be used in the context of feeding the results into `pgr_tsp()` function. We convert a text string of `x,y;x,y;...` into an array of points, then convert that into an array `vertex_id`, then create a distance matrix that gets feed into `pgr_tsp()` that returns the final result.

```sql
select * from pgr_tsp(
    (select dmatrix::float8[]
     from pgr_vidstodmatrix(
       'select id, source, target, cost, reverse_cost from edge_table',
       pgr_pointstovids(pgr_texttopoints('2,0;2,1;3,1;2,2;4,1;4,2;2,3;3,2', 0),
       'edge_table'),
       true, true, true) as dmatrix
    ),
    1)
);
seq | id
-----+----
 0 | 1
 1 | 0
 2 | 6
 3 | 3
 4 | 7
 5 | 5
 6 | 4
 7 | 2
(8 rows)
```

This example uses the **Sample Data** network.

See Also

- `pgr_vidsToDMatrix` - Creates a distances matrix from an array of `vertex_id`. 
• *pgr_textToPoints* - Create an array of points from a text string.
• *pgr_tsp* - Traveling Sales Person
The following functions are experimental

- They may lack documentation,
- Were created by GSoC students.
- they are unsupported.

- `pgr_vrpOneDepot` - VRP One Depot
- `pgr_vrppdtw` - Pickup and Delivery problem - Pickup and Delivery problem

### 10.1 pgr_vrpOneDepot

No documentation available from the original developer

**Warning:** this function is experimental and there is no assurance that it will work

- `pgr_costResult[]`

### 10.2 pgr_vrppdtw - Pickup and Delivery problem

#### 10.2.1 Name

`pgr_gsoc_vrppdtw` — Returns optimized solution

#### 10.2.2 Synopsis

Vehicle Routing Problem with Pickup and Delivery (VRPPD): A number of goods need to be moved from certain pickup locations to other delivery locations. The goal is to find optimal routes for a fleet of vehicles to visit the pickup and drop-off locations.

`pgr_gsoc_vrppdtw(text sql, integer , integer);`

#### 10.2.3 Description

- `sql` a SQL query, which should return a set of rows with the following columns:
```
select * from pgr_gsoc_vrppdtw('select * from customer order by id':::text, 25, 200);
```

Returns set of `pgr_costResult[]`:

- seq row sequence
- rid route ID
- nid node ID (-1 for the last row)
- cost cost to traverse to seq

### 10.2.4 Examples

```
SELECT * from pgr_gsoc_vrppdtw('select * from customer order by id':::text, 25, 200);
```

<table>

### 10.2.5 See Also

- `pgr_costResult[]`
Proposed functions: Proposed by Zia Mohammed

About this proposal:

- Author: Zia Mohammed.
- Status: Needs a lot of testing. I am working on that.
- I did not add automated test.
- Temporary name: pgr_labelGraph
- Need: I need feedback from the community.
- **pgr_labelGraph** - Analyze / label subgraphs within a network

### 11.1 pgr_labelGraph

#### 11.1.1 Name

**pgr_labelGraph** — Locates and labels sub-networks within a network which are not topologically connected. Must be run after **pgr_createTopology()**. No use of geometry column. Only **id**, **source** and **target** columns are required.

#### 11.1.2 Synopsis

The function returns:

- **OK** when a column with provided name has been generated and populated successfully. All connected edges will have unique similar integer values. In case of **rows_where** condition, non participating rows will have -1 integer values.
- **FAIL** when the processing cannot be finished due to some error. Notice will be thrown accordingly.
- **rows_where** condition generated 0 rows when passed SQL condition has not been fulfilled by any row.

```sql
varchar pgr_labelGraph(text, text, text, text, text, text, text)
```

#### 11.1.3 Description

A network behind any routing query may consist of sub-networks completely isolated from each other. Possible reasons could be:

- An island with no bridge connecting to the mainland.
• An edge or mesh of edges failed to connect to other networks because of human negligence during data generation.
• The data is not properly noded.
• Topology creation failed to succeed.

pgr_labelGraph() will create an integer column (with the name provided by the user) and will assign same integer values to all those edges in the network which are connected topologically. Thus better analysis regarding network structure is possible. In case of rows_where condition, non participating rows will have -1 integer values.

Prerequisites: Must run pgr_createTopology() in order to generate source and target columns. Primary key column id should also be there in the network table.

Function accepts the following parameters:

edge_table text Network table name, with optional schema name.
id text Primary key column name of the network table. Default is id.
source text Source column name generated after pgr_createTopology(). Default is source.
target text Target column name generated after pgr_createTopology(). Default is target.
subgraph text Column name which will hold the integer labels for each sub-graph. Default is subgraph.
rows_where text The SQL where condition. Default is true, means the processing will be done on the whole table.

11.1.4 Possible Usage

– The following should be OK

```sql
select pgr_labelGraph('ways');
select pgr_labelGraph('Ways');
select pgr_labelGraph('ways', 'id');
select pgr_labelGraph('ways', 'id', 'source');
select pgr_labelGraph('ways', 'id', 'source', 'target');
select pgr_labelGraph('ways', 'id', 'source', 'target', 'subgraph');
select pgr_labelGraph('ways', 'id', 'source', 'target', 'subgraph', 'id<100');
```

– When table located in another schema e03

```sql
select pgr_labelGraph('e03.ways');
select pgr_labelGraph('e03.Ways');
select pgr_labelGraph('e03.ways', 'id');
select pgr_labelGraph('e03.ways', 'id', 'source');
select pgr_labelGraph('e03.ways', 'id', 'source', 'target');
select pgr_labelGraph('e03.ways', 'id', 'source', 'target', 'subgraph');
select pgr_labelGraph('e03.ways', 'id', 'source', 'target', 'subgraph', 'id<100');
```

– When using the named notation

```sql
select pgr_labelGraph('e03.calles', target:='destino', subgraph:='subgraph', id:='gido', source:='salida');
select pgr_labelGraph('e03.calles', rows_where:='gido<100', id:='gido', source:='salida', target:='destino', subgraph:='subgraph');
```

– The following should FAIL

```sql
select pgr_labelGraph('id', 'ways');
select pgr_labelGraph('ways', 'id', 'sourc', 'target');
select pgr_labelGraph('ways', 'id', 'source', 'Target');
select pgr_labelGraph('ways', 'id', 'source', 'target', 'subgraph', 'id<');
```
– When table located in another schema e03

```sql
select pgr_labelGraph('e03.calles');
select pgr_labelGraph('e03.Calles');
select pgr_labelGraph('id', 'e03.calles');
select pgr_labelGraph('e03.calles', 'id', 'sourc', 'target');
select pgr_labelGraph('e03.calles', 'gido', 'source', 'target', 'subgraph', 'id<');
select pgr_labelGraph('e03.calles', 'gid', 'salida', 'destino', 'subgraph', 'id<10');
select pgr_labelGraph('e03.calles', 'gid', 'salida', 'destino', 'subgraph', 'id<10 AND id>100');
```

– When using the named notation

```sql
select pgr_labelGraph('e03.calles', target:='destino', subgraph:='subgraph', id:='gido');
select pgr_labelGraph('e03.calles', target:='destino', subgraph:='subgraph', id:='gido', source:='salido');
select pgr_labelGraph(rows_where:='gido<100', id:='gido', source:='salida', 'e03.calles', target:='destino', subgraph:='subgraph');
```

– The following should return “rows_where condition generated 0 rows”

```sql
select pgr_labelGraph('ways', 'id', 'source', 'target', 'subgraph', 'id<10 AND id>100');
select pgr_labelGraph('e03.calles', id:='gido', rows_where:='gido<100 AND gido>200', source:='salida');
```

### 11.1.6 See Also

- `pgr_createTopology`\(^1\) to create the topology of a table based on its geometry and tolerance value.

### 11.2 Developers’s Functions

Functions to help you develop a wrapper or a recipe

- `pgr_getColumnName` - to get the name of the column as is stored in the postgres administration tables.
- `pgr_getTableName` - to retrieve the name of the table as is stored in the postgres administration tables.
- `pgr_isColumnIndexed` - to check if the column is indexed.

\(^1\) [https://github.com/Zia-/pgrouting/blob/develop/src/common/sql/pgrouting_topology.sql](https://github.com/Zia-/pgrouting/blob/develop/src/common/sql/pgrouting_topology.sql)
• `pgr_isColumnInTable` - to check only for the existence of the column.
• `pgr_pointToId` - to insert/get the id of the inserted point in a vertices table.
• `pgr_quote_ident` - to quote the input text to be used as an identifier in an SQL statement string.
• `pgr_versionless` - to compare two version numbers.
• `pgr_startPoint` - to get the start point of a (multi)linestring.
• `pgr_endPoint` - to get the end point of a (multi)linestring.

### 11.2.1 pgr_getColumnName

#### Name

**pgr_getColumnName** — Retrieves the name of the column as is stored in the postgres administration tables.

**Note:** This function is intended for the developer’s aid.

**Warning:** This function is deprecated in 2.1. Use `_pgr_getColumnName` instead

#### Synopsis

Returns a text containing the registered name of the column.

```sql
text pgr_getColumnName(tab text, col text);
```

#### Description

**Parameters**

- `tab` text: table name with or without schema component.
- `col` text: column name to be retrieved.

**Returns**

- text: containing the registered name of the column.
- NULL when:
  - The table “tab” is not found or
  - Column “col” is not found in table “tab” in the postgres administration tables.

#### History

- New in version 2.0.0

#### Examples

```sql
SELECT pgr_getColumnName('edge_table','the_geom');
```

```
<table>
<thead>
<tr>
<th>the_geom</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1 row)</td>
</tr>
</tbody>
</table>
```
The queries use the Sample Data network.

**See Also**

- Developer’s Guide for the tree layout of the project.
- `pgr_isColumnInTable` to check only for the existance of the column.
- `pgr_getTableName` to retrieve the name of the table as is stored in the postgres administration tables.

### 11.2.2 pgr_getTableName

**Name**

pgr_getTableName — Retrieves the name of the column as is stored in the postgres administration tables.

**Note:** This function is intended for the developer’s aid.

**Warning:** This function is deprecated in 2.1 Use `_pgr_getTableName` instead

**Synopsis**

Returns a record containing the registered names of the table and of the schema it belongs to.

```
(text sname, text tname) pgr_getTableName(text tab)
```

**Description**

**Parameters**

- **tab** text: table name with or without schema component.

**Returns**

- **sname**
  - text: containing the registered name of the schema of table “tab”.
    - when the schema was not provided in “tab” the current schema is used.
  - NULL when:
    - The schema is not found in the postgres administration tables.

- **tname**
  - text: containing the registered name of the table “tab”.
  - NULL when:
    - The schema is not found in the postgres administration tables.
    - The table “tab” is not registered under the schema `sname` in the postgres administration tables.

---

11.2. Developers’s Functions 139
History

- New in version 2.0.0

Examples

```sql
SELECT * from pgr_getTableName('edge_table');
```

```
sname | tname
-------+-------
public | edge_table
(1 row)
```

```sql
SELECT * from pgr_getTableName('EdgeTable');
```

```
sname | tname
-------+-------
public |       
(1 row)
```

```sql
SELECT * from pgr_getTableName('data.Edge_Table');
```

```
sname | tname
-------+-------
       |       
(1 row)
```

The examples use the Sample Data network.

See Also

- Developer’s Guide for the tree layout of the project.
- `pgr_isColumnInTable` to check only for the existance of the column.
- `pgr_getTableName` to retrieve the name of the table as is stored in the postgres administration tables.

### 11.2.3 pgr_isColumnIndexed

#### Name

pgr_isColumnIndexed — Check if a column in a table is indexed.

**Note:** This function is intended for the developer’s aid.

**Warning:** This function is deprecated in 2.1 Use `pgr_isColumnIndexed` instead

#### Synopsis

Returns true when the column “col” in table “tab” is indexed.

```sql
boolean pgr_isColumnIndexed(text tab, text col);
```
Description

**tab**  text  Table name with or without schema component.

**col**  text  Column name to be checked for.

Returns:

- **true** when the column “col” in table “tab” is indexed.
- **false** when:
  - The table “tab” is not found or
  - Column “col” is not found in table “tab” or
  - Column “col” in table “tab” is not indexed

History

- New in version 2.0.0

Examples

```sql
SELECT pgr_isColumnIndexed('edge_table','x1');

pgr_iscolumnindexed
---------------------
  f
  (1 row)

SELECT pgr_isColumnIndexed('public.edge_table','cost');

pgr_iscolumnindexed
---------------------
  f
  (1 row)
```

The example use the *Sample Data* network.

See Also

- *Developer’s Guide* for the tree layout of the project.
- *pgr_isColumnInTable* to check only for the existance of the column in the table.
- *pgr_getColumnName* to get the name of the column as is stored in the postgres administration tables.
- *pgr_getTableName* to get the name of the table as is stored in the postgres administration tables.

### 11.2.4 pgr_isColumnInTable

**Name**

*pgr_isColumnInTable* — Check if a column is in the table.

**Note:** This function is intended for the developer’s aid.

**Warning:** This function is deprecated in 2.1 Use `_pgr_isColumnInTable` instead
Synopsis

Returns true when the column “col” is in table “tab”.

```plaintext
boolean pgr_isColumnInTable(text tab, text col);
```

Description

- **tab** text: Table name with or without schema component.
- **col** text: Column name to be checked for.

Returns:

- true when the column “col” is in table “tab”.
- false when:
  - The table “tab” is not found or
  - Column “col” is not found in table “tab”

History

- New in version 2.0.0

Examples

```sql
SELECT pgr_isColumnInTable('edge_table','x1');
```

```
<table>
<thead>
<tr>
<th>pgr_iscolumnintable</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
</tr>
</tbody>
</table>
```

```
SELECT pgr_isColumnInTable('public.edge_table','foo');
```

```
<table>
<thead>
<tr>
<th>pgr_iscolumnintable</th>
</tr>
</thead>
<tbody>
<tr>
<td>f</td>
</tr>
</tbody>
</table>
```

The example use the Sample Data network.

- [pgr_getTableName](#) to get the name of the table as is stored in the postgres administration tables.

11.2.5 pgr_pointToId

Name

pgr_pointToId — Inserts a point into a vertices table and returns the corresponding id.
Note: This function is intended for the developer’s aid. Use `pgr_createTopology` or `pgr_createVerticesTable` instead.

Warning: This function is deprecated in 2.1

Synopsis

This function returns the id of the row in the vertices table that corresponds to the point geometry

```sql
bigint pgr_pointToid(geometry point, double precision tolerance, text vertname text, integer srid)
```

Description

- **point** geometry “POINT” geometry to be inserted.
- **tolerance** float8 Snapping tolerance of disconnected edges. (in projection unit)
- **vertname** text Vertices table name WITH schema included.
- **srid** integer SRID of the geometry point.

This function returns the id of the row that corresponds to the point geometry

- When the point geometry already exists in the vertices table vertname, it returns the corresponding id.
- When the point geometry is not found in the vertices table vertname, the function inserts the point and returns the corresponding id of the newly created vertex.

Warning: The function do not perform any checking of the parameters. Any validation has to be done before calling this function.

History

- Renamed in version 2.0.0

See Also

- `Developer’s Guide` for the tree layout of the project.
- `pgr_createVerticesTable` to create a topology based on the geometry.
- `pgr_createTopology` to create a topology based on the geometry.

11.2.6 pgr_quote_ident

Name

`pgr_quote_ident` — Quotes the input text to be used as an identifier in an SQL statement string.

Note: This function is intended for the developer’s aid.

Warning: This function is deprecated in 2.1 Use `_pgr_quote_ident` instead
Synopsis

Returns the given identifier `idname` suitably quoted to be used as an identifier in an SQL statement string.

```plaintext
text pgr_quote_ident(text idname);
```

Description

Parameters

`idname` text Name of an SQL identifier. Can include . dot notation for schemas.table identifiers

Returns the given string suitably quoted to be used as an identifier in an SQL statement string.

- When the identifier `idname` contains on or more . separators, each component is suitably quoted to be used in an SQL string.

History

- New in version 2.0.0

Examples

Everything is lower case so nothing needs to be quoted.

```sql
SELECT pgr_quote_ident('the_geom');
pgr_quote_ident
---------------
   the_geom
(1 row)

SELECT pgr_quote_ident('public.edge_table');
pgr_quote_ident
-------------------
  public.edge_table
(1 row)
```

The column is upper case so its double quoted.

```sql
SELECT pgr_quote_ident('edge_table.MYGEOM');
pgr_quote_ident
----------------
  edge_table."MYGEOM"
(1 row)

SELECT pgr_quote_ident('public.edge_table.MYGEOM');
pgr_quote_ident
-------------------
  public.edge_table."MYGEOM"
(1 row)
```

The schema name has a capital letter so its double quoted.
SELECT pgr_quote_ident('Myschema.edge_table');

  pgr_quote_ident
----------------------
  "Myschema".edge_table
(1 row)

Ignores extra . separators.

SELECT pgr_quote_ident('Myschema...edge_table');

  pgr_quote_ident
---------------------
  "Myschema".edge_table
(1 row)

See Also

- Developer’s Guide for the tree layout of the project.
- pgr_getTableName to get the name of the table as is stored in the postgres administration tables.

11.2.7 pgr_versionless

Name

pgr_versionless — Compare two version numbers.

Note: This function is intended for the developer’s aid.

Warning: This function is deprecated in 2.1. Use _pgr_versionless instead

Synopsis

Returns true if the first version number is smaller than the second version number. Otherwise returns false.

boolean pgr_versionless(text v1, text v2);

Description

- v1 text first version number
- v2 text second version number

History

- New in version 2.0.0

Examples
SELECT pgr_versionless('2.0.1', '2.1');

pgr_versionless
-----------------
t
(1 row)

See Also

- Developer’s Guide for the tree layout of the project.
- pgr_version to get the current version of pgRouting.

11.2.8 pgr_startPoint

Name

pgr_startPoint — Returns a start point of a (multi)linestring geometry.

Note: This function is intended for the developer’s aid.

Warning: This function is deprecated in 2.1 Use _pgr_startPoint instead

Synopsis

Returns the geometry of the start point of the first LINestring of geom.

geometry pgr_startPoint(geometry geom);

Description

Parameters

geom geometry Geometry of a MULTILINESTRING or LINestring.

Returns the geometry of the start point of the first LINestring of geom.

History

- New in version 2.0.0

See Also

- Developer’s Guide for the tree layout of the project.
- pgr_endPoint to get the end point of a (multi)linestring.
11.2.9 pgr_endPoint

Name

pgr_endPoint — Returns an end point of a (multi)linestring geometry.

Note: This function is intended for the developer’s aid.

Warning: This function is being deprecated on 2.1. Use _pgr_endPoint instead

Synopsis

Returns the geometry of the end point of the first LINESTRING of geom.

\texttt{pgr_startPoint(\text{geometry geom});}

Description

Parameters

\texttt{geom} \hspace{1em} \texttt{Geometry of a MULTILINESTRING or LINESTRING.}

Returns the geometry of the end point of the first LINESTRING of \texttt{geom}.

History

• New in version 2.0.0

See Also

• \textit{Developer’s Guide} for the tree layout of the project.
• \textit{pgr_startPoint} to get the start point of a (multi)linestring.
12.1 Discontinued Functions

Especially with new major releases functionality may change and functions may be discontinued for various reasons. Functionality that has been discontinued will be listed here.

12.1.1 Shooting Star algorithm

- **Version** Removed with 2.0.0
- **Reasons** Unresolved bugs, no maintainer, replaced with *pgr_trsp - Turn Restriction Shortest Path (TRSP)*
- **Comment** Please *contact us* if you’re interested to sponsor or maintain this algorithm. The function signature is still available in `common_legacy` but it is just a wrapper that throws an error. We have not included any of the old code for this in this release.
Developers’s Functions

**Warning:** In V3.0 This function are going to be discontinued. Use the already available underscored version instead.

**Warning:** Developers’s Functions documentation is going to be deleted from the pgRouting documentation in V3.0

The following functions are used internally the topology functions.

- `pgr_getColumnName` - to get the name of the column as is stored in the postgres administration tables.
- `pgr_getTableName` - to retrieve the name of the table as is stored in the postgres administration tables.
- `pgr_isColumnIndexed` - to check if the column is indexed.
- `pgr_isColumnInTable` - to check only for the existence of the column.
- `pgr_pointToId` - to insert/get the id of the inserted point in a vertices table.
- `pgr_quote_ident` - to quote the input text to be used as an identifier in an SQL statement string.
- `pgr_versionless` - to compare two version numbers.
- `pgr_startPoint` - to get the start point of a (multi)linestring.
- `pgr_endPoint` - to get the end point of a (multi)linestring.

### 13.1 Developer’s Guide

#### 13.1.1 Source Tree Layout

`cmake/` cmake scripts used as part of our build system.

`src/` This is the algorithm source tree. Each algorithm is to be contained in its own sub-tree with /doc, /sql, /src, and /test sub-directories.

For example:

- `src/dijkstra` Main directory for dijkstra algorithm.
- `src/dijkstra/doc` Dijkstra’s documentation directory.
- `src/dijkstra/src` Dijkstra’s C and/or C++ code.
- `src/dijkstra/sql` Dijkstra’s sql code.
- `src/dijkstra/test` Dijkstra’s tests.
**13.1.2 Tools**

*tools/* Miscellaneous scripts and tools.

**pre-commit**

To keep version/branch/commit up to date install please do the following:

```bash
cp tools/pre-commit .git/hooks/pre-commit
```

After each commit a the file `VERSION` will remain. (The hash number will be one behind)

**tester**

The tester is executed from the top level of the tree layout:

```bash
tools/test-runner.pl --help
```

**doxygen**

**Warning:** *Developers’s Functions* documentation is going to be deleted from the pgRouting documentation and included in the doxygen documentation.

To use doxygen:

```bash
cd tools/doxygen/
made
```

The code’s documentation can be found in:

```bash
build/doxy/html/index.html
```

**cpplint**

We try to follow the following guidelines for C++ coding:

https://google-styleguide.googlecode.com/svn/trunk/cppguide.html

Sample use:

```bash
python cpplint.py ../src/dijkstra/src/dijkstra_driver.h
../src/dijkstra/src/dijkstra_driver.h:34: Lines should be <= 80 characters long [whitespace/line_length]
../src/dijkstra/src/dijkstra_driver.h:40: Line ends in whitespace. Consider deleting these extra spaces [whitespace/end_of_line]
Done processing ../src/dijkstra/src/dijkstra_driver.h
Total errors found: 2
```

- Maybe line 34 is a very complicated calculation so you can just ignore the message
- Delete whitespace at end of line is easy fix.
- Use your judgement!!!

Some files like `postgres.h` are system dependant so don’t include the directory.
Other tools

Tools like:

- doit
- winnie
- publish_doc.sh

are very specific for the deployment of new versions, so please ask first!

13.1.3 Documentation Layout

Note: All documentation should be in reStructuredText format. See: <http://docutils.sf.net/rst.html> for introductory docs.

Documentation is distributed into the source tree. This top level “doc” directory is intended for high level documentation cover subjects like:

- Compiling and testing
- Installation
- Tutorials
- Users’ Guide front materials
- Reference Manual front materials
- etc

Since the algorithm specific documentation is contained in the source tree with the algorithm specific files, the process of building the documentation and publishing it will need to assemble the details with the front material as needed.

Also, to keep the “doc” directory from getting cluttered, each major book like those listed above, should be contained in a separate directory under “doc”. Any images or other materials related to the book should also be kept in that directory.

13.1.4 Testing Infrastructure

There is a very basic testing infrastructure put in place. Here are the basics of how it works. We need more test cases. Longer term we should probably get someone to setup travis-ci or jenkins testing frameworks.

Here is the graph for the TRSP tests.
Tests are run via the script at the top level tools/test-runner.pl and it runs all the test configured tests and at the moment just dumps the results structure of the test. This can be prettied up later.

It also assumes that you have installed the libraries as it tests using the installed postgresql. This probably needs to be made smarter so we can test out of the build tree. I’ll need to think about that.

Basically each .../test/ directory should include one test.conf file that is a perl script fragment that defines what data files to load and what tests to run. I have built in some mechanisms to allow test and data to be pg version and postgis version specific, but I’m not using that yet. So for example, core/trsp/test/test-any-00.data is a sql plain text dump that will load and needed data for a set of tests. This is also the graph in the image above. You can specify multiple files to load, but as a group they need to have unique names.

core/trsp/test/test-any-00.test is a sql command to be run. It will get run as:

```
psql ... -A -t -q -f file.test dbname > tmpfile
diff -w file.rest tmpfile
```

Then if there is a difference then an test failure is reported.

Release Notes

- pgRouting 2.1.0 Release Notes
13.2 Release Notes

13.2.1 pgRouting 2.1.0 Release Notes

With the release of pgRouting 2.1.0 fixes some bugs and issues.

- To see the full list of changes check the list of Git commits[1] on Github.
- To see the issues closed by this release see the Git closed issues[2] on Github.
- For important changes see the following release notes.

Release Notes

- A C and C++ library for developer was created
  - encapsulates postgresQL related functions
  - encapsulates Boost.Graph graphs
    - Directed Boost.Graph
    - Undirected Boost.graph.
  - allow any-integer in the id’s
  - allow any-numerical on the cost/reverse_cost columns
- Three Functions where completly re-factored using the developers library and functionality was added.
  - pgr_dijkstra
  - pgr_ksp
  - pgr_drivingDistance
- Improved - Alphashape function now can generate better (multi)polygon with holes and alpha parameter.
- Instead of generating many libraries: - All functions are encapsulated in one library - The library has a the prefix 2-1-0
- Added proposed functions to be evaluated:
  - Proposed functions from Steve Woodbridge, (Classified as Convinience by the author.)
    - pgr_pointToEdgeNode - convert a point geometry to a vertex_id based on closest edge.
    - pgr_flipEdges - flip the edges in an array of geometries so the connect end to end.
    - pgr_textToPoints - convert a string of x,y;x,y;... locations into point geometries.
    - pgr_pointsToVids - convert an array of point geometries into vertex ids.
    - pgr_pointsToDMatrix - Create a distance matrix from an array of points.
    - pgr_vidsToDMatrix - Create a distance matrix from an array of vertex_id.

[2]https://github.com/pgRouting/pgrouting/issues/?q=is%3Aissue+milestone%3A%22Release+2.1.0%22+is%3Aclosed
* pgr vidsToDMatrix - Create a distance matrix from an array of vertix_id.

- Added proposed functions from GSoc Projects:
  - pgr_vrppdtw

- Removed the 1.x legacy functions

- Some bug fixes in other functions

13.2.2 pgRouting 2.0 Release Notes

With the release of pgRouting 2.0 the library has abandoned backwards compatibility to pgRouting 1.x releases. We did this so we could restructure pgRouting, standardize the function naming, and prepare the project for future development. As a result of this effort, we have been able to simplify pgRouting, add significant new functionality, integrate documentation and testing into the source tree and make it easier for multiple developers to make contribution.

For important changes see the following release notes. To see the full list of changes check the list of Git commits\(^3\) on Github.

Changes for 2.0.0

- Graph Analytics - tools for detecting and fixing connection some problems in a graph
- A collection of useful utility functions
- Two new All Pairs Short Path algorithms (pgr_apspJohnson, pgr_apspWarshall)
- Bi-directional Dijkstra and A-star search algorithms (pgr_bdAstar, pgr_bDijkstra)
- One to many nodes search (pgr_kDijkstra)
- K alternate paths shortest path (pgr_ksp)
- New TSP solver that simplifies the code and the build process (pgr_tsp), dropped “Gaul Library” dependency
- Turn Restricted shortest path (pgr_trsp) that replaces Shooting Star
- Dropped support for Shooting Star
- Built a test infrastructure that is run before major code changes are checked in
- Tested and fixed most all of the outstanding bugs reported against 1.x that existing in the 2.0-dev code base.
- Improved build process for Windows
- Automated testing on Linux and Windows platforms trigger by every commit
- Modular library design
- Compatibility with PostgreSQL 9.1 or newer
- Compatibility with PostGIS 2.0 or newer
- Installs as PostgreSQL EXTENSION
- Return types refactored and unified
- Support for table SCHEMA in function parameters
- Support for st_ PostGIS function prefix
- Added pgr_ prefix to functions and types
- Better documentation: http://docs.pgrouting.org

\(^3\)https://github.com/pgRouting/pgrouting/commits
13.2.3 pgRouting 1.x Release Notes

The following release notes have been copied from the previous RELEASE_NOTES file and are kept as a reference. Release notes starting with version 2.0.0 will follow a different schema.

Changes for release 1.05

• Bugfixes

Changes for release 1.03

• Much faster topology creation
• Bugfixes

Changes for release 1.02

• Shooting\* bugfixes
• Compilation problems solved

Changes for release 1.01

• Shooting\* bugfixes

Changes for release 1.0

• Core and extra functions are separated
• Cmake build process
• Bugfixes

Changes for release 1.0.0b

• Additional SQL file with more simple names for wrapper functions
• Bugfixes

Changes for release 1.0.0a

• Shooting\* shortest path algorithm for real road networks
• Several SQL bugs were fixed

Changes for release 0.9.9

• PostgreSQL 8.2 support
• Shortest path functions return empty result if they couldn’t find any path
Changes for release 0.9.8

- Renumbering scheme was added to shortest path functions
- Directed shortest path functions were added
- routing_postgis.sql was modified to use dijkstra in TSP search

Indices and tables

- genindex
- search
